This report gives the latest information on how Aboriginal and Torres Strait Islander people in New South Wales are faring according to various measures of health status and outcomes, determinants of health, and health system performance. Indicators are based on the Aboriginal and Torres Strait Islander Health Performance Framework. The report highlights the main areas of improvement, and continuing concern.

Acknowledgments

The authors of this report are Jacqui Aldis, Josh Alexander, Therese Bourke, Ilona Brockway, Prajali Dangol, Tracy Dixon, Kim Dobbie, Tetteh Dugbaza, Elizabeth Hynes, Amitha Jason, Jakub Kielbasa, Lisa Irvine, Quan Nguyen, Chun Oberst, Ruth Penm, Anh Pham-Waddell, Ronda Ramsay, Jan Watson, Qinghe Yin and Bronwyn Wyatt. Thanks are extended to Fadwa Al-Yaman, who provided ongoing guidance and comments.

Thanks for the supply of data and review of relevant material are extended to units within the Australian Institute of Health and Welfare.

The following organisations provided data for various sections of the report:

- Australian and New Zealand Dialysis and Transplant Registry
- Australian Bureau of Statistics
- Australian Capital Territory Health
- Australian Curriculum, Assessment and Reporting Authority
- Australian General Practice Accreditation Limited
- Australian General Practice Statistics and Classification Centre
- Australian Government Department of Education and Training
- Australian Government Department of Health
- Australian Government Department of Human Services
- Australian Government Department of Social Services
- Australian Institute of Criminology
- GPA Accreditation Plus
- National Centre for Vocational Education and Research
- National Notifiable Diseases Surveillance System
- New South Wales Health
- Northern Territory Acute Rheumatic Fever and Rheumatic Heart Disease Program
- Northern Territory Department of Health
- Office of the Registrar of Indigenous Corporations
- Primary Health Care Research and Information Service
- Queensland Health
- Rural Health Workforce Australia
- South Australian Department for Health and Ageing
- Tasmanian Department of Health and Human Services
- The Kirby Institute, University of New South Wales
- Victorian Department of Health and Human Services
- Western Australian Department of Health.

This work received financial support from the New South Wales Department of Health, and the Australian Government Department of the Prime Minister and Cabinet. Thanks to staff of both agencies for providing feedback on the report.

Summary

The Aboriginal and Torres Strait Islander Health Performance Framework 2017 report for New South Wales finds both areas of improvement and areas of concern in the health of Aboriginal and Torres Strait Islander people living in New South Wales (Table S1).

Areas of improvement for New South Wales include:

- Deaths due to circulatory diseases—the leading cause of death for Indigenous Australians—fell by 27% between 2006 and 2015 (Table 1.23.28).
- Medicare-recorded health assessments for Indigenous Australians rose significantly between 2006–07 and 2015–16, from 30 to 247 per 1,000 (Table 3.04.3).
- A decrease in the infant mortality rate, from 11.7 per 1,000 live births in 1998–2000 to 5.2 per 1,000 live births in 2013–2015 (Table 1.20.9). The gap in the low birthweight rate for babies born to Indigenous mothers, compared with non-Indigenous mothers fell from 7.3% in 2001 to 5.0% in 2014 (Table 1.01.3).

Areas of concern for New South Wales include:

- The age-standardised proportion of Indigenous women smoking during pregnancy (45%) was 4 times the rate for non-Indigenous women (11%) in 2014 (Table 2.21.1).
- Death rates from chronic diseases in 2011–2015 were much higher for Indigenous Australians than for non-Indigenous Australians—more than 3 times as high for diabetes (50 compared with 15 per 100,000), and almost twice as high for respiratory diseases (90 compared with 51 per 100,000) (Table 1.23.2).
- Death rates for some cancers in 2011–2015 were much higher for Indigenous Australians than for non-Indigenous Australians—more than 3 times as high for cervical cancer (3.1 compared with 0.9 per 100,000), and almost twice as high for lung cancer (56 compared with 31 per 100,000) (Table 1.23.2).
- The incidence of end-stage kidney disease for Indigenous Australians rose from 6.5 per 100,000 in 1996 to 14 per 100,000 in 2014 (Table 1.10.15).
- Indigenous Australians had higher rates of hospitalisation for injury than non-Indigenous Australians (38 compared with 25 per 1,000) between July 2013 and June 2015. The most common injuries were falls, assault, exposure to inanimate mechanical forces, complications of medical and surgical care, and transport accidents (tables 1.03.3 and 1.03.7 NSW).
- Indigenous Australians had lower rates of hospital procedures than non-Indigenous Australians (63% compared with 80%) between July 2013 and June 2015 (Table 3.06.1).
- The unemployment rate for people aged 15–64 continued to be higher for Indigenous than non-Indigenous Australians (15% compared with 6% in 2014–15) (Table 2.07.5).

* Represents statistically significant differences between Indigenous and non-Indigenous data at the p < 0.05 level (see Glossary).
(a) Indigenous crude rates are presented unless otherwise indicated in the measure description.
(b) Age-standardised gap is the Indigenous age-standardised rate minus the non-Indigenous age-standardised rate. Age-standardised comparisons take into account the differences in the age structure between the Indigenous and non-Indigenous populations. The age-standardised gap cannot be used to calculate the non-Indigenous rate. Age-standardisation is not appropriate for the following measures, and gaps calculated on crude rates have been presented for: low birthweight, life expectancy, housing, employment, education, motor vehicles, income, children in households with daily smokers, child health checks, emergency department presentations, health workforce, expenditure, and higher education data. The age-standardised gap is positive (+) when the Indigenous rate is higher than the non-Indigenous rate, and negative (–) when the Indigenous rate is lower than the non-Indigenous rate.
(c) The differences between Indigenous and non-Indigenous Australians were not tested for statistical significance.
(d) Data are reported for New South Wales, Victoria, Queensland, Western Australia and the Northern Territory only.
(e) Data for New South Wales also include data for the Australian Capital Territory.
(f) National life expectancy estimates presented in this table enable effective comparison with state and territory estimates. However estimates in measure 1.19 have been calculated using a different method and enable comparison across 2 time points.

\[ xiii \]
Introduction

This is the 5th report in a series that provides information on various measures of health status, determinants of health, and the health system performance for Aboriginal and Torres Strait Islander people in New South Wales.

The report is based on the *Aboriginal and Torres Strait Islander Health Performance Framework 2017 report, detailed analyses*, the 6th in a series of reports against the Aboriginal and Torres Strait Islander Health Performance Framework, which are published every 2 years.

Analysis presented in this report includes jurisdiction-specific measures, and how they compare with national measures. Detailed Excel tables to support the analysis can be found at <www.aihw.gov.au/reports/indigenous-health-welfare/health-performance-framework/contents>.

The Health Performance Framework comprises 3 tiers:

- **Tier 1**—Health status and outcomes. This tier covers the prevalence of health conditions (for example, circulatory disease, diabetes), human function (for example, disability), life expectancy, wellbeing, and deaths. It aims to provide an overall indication of current health status and recent trends on issues such as child and maternal health, chronic diseases, injury, communicable diseases, and social and emotional wellbeing.

- **Tier 2**—Determinants of health. This tier covers determinants of health that focus on factors outside the health system, but affect the health of Aboriginal and Torres Strait Islander people. This includes socioeconomic status (for example, income and education), environmental factors (for example, overcrowding), community capacity (for example, child protection), health behaviours (for example, risky alcohol consumption or dietary behaviour) and person-related factors (for example, prevalence of overweight and obesity). Such factors have been shown to have a strong association with disease and ill health.

- **Tier 3**—Health system performance. This tier covers the performance of the health system, including population health, primary health care, and secondary/tertiary care services. It covers 6 areas: effectiveness of health services, responsiveness of health services to Aboriginal and Torres Strait Islander communities and individuals, accessibility of services, continuity, capability, and sustainability. This tier includes measures that deal with various programs and service types, including child and maternal health, early detection and chronic disease management, continuous care, access to secondary/tertiary care, health workforce and expenditure. The safety and quality of health care is measured through the Australian Safety and Quality Framework for Health Care <http://www.safetyandquality.gov.au>.

The tiers and domains of the Health Performance Framework and selected measures are shown in Figure 1. There are currently 68 measures that can be reported at the national level but not all can be reported for individual jurisdictions due to data availability and quality issues. Information on why these indicators were selected is in the Aboriginal and Torres Strait Islander Health Performance Framework 2017 policy report (AHMAC 2017).

Figure 1: Aboriginal and Torres Strait Islander Health Performance Framework Measures
Demographic information

The preliminary estimated resident Aboriginal and Torres Strait Islander population of New South Wales as at 30 June 2016 was about 265,600 people (ABS 2017), accounting for one-third (33%) of Australia’s Indigenous population. Indigenous Australians represent 3.4% of the New South Wales population, similar to the proportion of Indigenous Australians in the total Australian population (3.3%) (Table 1 NSW).

(a) Includes territories other than New South Wales, Victoria, Queensland, South Australia, Western Australia, Tasmania, the Northern Territory and the Australian Capital Territory.

Australia’s Aboriginal and Torres Strait Islander population has an age structure that is significantly younger than that of other Australians.

For example, in New South Wales Aboriginal and Torres Strait Islander people aged under 15 constitute almost 35% of the Indigenous population, whereas this age group represents just over 18% of the non-Indigenous population.

Conversely, people aged 65 and over comprise 4.8% of the Indigenous population in New South Wales, compared with 16% of the non-Indigenous population (Figure 2).

The 2016 Estimated Resident Population by remoteness categories was not available at the time of publication of this report. In 2011 in New South Wales, the vast majority of Aboriginal and Torres Strait Islander people lives in Major cities (45%), Inner regional (34%), and Outer regional (17%) areas, with less than 5% living in Remote and Very remote areas.

In comparison, more than three-quarters of the total Indigenous population in Australia lives in Major cities (35%), Inner regional (22%), and Outer regional (22%) areas, with about one-fifth living in Remote (8%) and Very remote areas (14%) (Table 2 NSW).

Source: AIHW analysis of ABS population estimates based on 2011 Census.
Note: Proportions are calculated separately for Indigenous and non-Indigenous populations. For example, males aged 0–4 years represent 6% of the Indigenous population of Australia, and just over 3% of the non-Indigenous population.

Source: AIHW analysis of ABS preliminary population estimates based on 2016 Census, Table 3 NSW.

Figure 2: Population profile, by Indigenous status, age and sex, New South Wales and Australia, 30 June 2016
Structure of this report

This report presents the most recent data available at the time of writing, which varies by data source (see Table S1 for the most recent year/period for which key statistics are reported). Analyses for each measure are presented in order of Tier 1—Health status and outcomes, Tier 2—Determinants of health, and Tier 3—Health system performance.

The format of this report is different to previous Health Performance Framework reports for New South Wales. More graphs are included, and key findings for Australia are presented in each measure to enable comparison of Indigenous Australians in New South Wales with Indigenous Australians nationally. In each measure, where available, trend data are highlighted in the text, and, where possible, the analysis focuses on the gap between Indigenous and non-Indigenous Australians.

Detailed Excel tables to support the analyses presented in this report can be found at <www.aihw.gov.au/reports/indigenous-health-welfare/health-performance-framework/contents>.

Interpreting the data in this report

Data sources and limitations

Data in this report come from various administrative data sets and surveys, all of which have limitations that should be considered when interpreting the results. A brief description of the major data sources used in this report is at Appendix 1, while a more detailed description of all data sources and comments on data quality can be found at <www.aihw.gov.au/reports/indigenous-health-welfare/health-performance-framework/contents>. The data in this report was progressively collected and different data sources have different date ranges. The most recent data in this report is 2016.

Administrative data sources

Health-related administrative data sets used for this report include the AIHW’s National Hospital Morbidity Database, the National Mortality Database, the Community Mental Health Care Database, the National Perinatal Data Collection, the Australia and New Zealand Dialysis and Transplant Registry, the National Notifiable Diseases Surveillance System, the Online Services Report data collection, and Medicare databases. Administrative data related to education include the Australian Bureau of Statistics’ National Schools Statistics Collection, Department of Education and Training Higher Education Student Statistics Collection, and the National Vocational Education and Training database. Community services related data include the National Child Protection Data collections.

The main limitation in most of these administrative data collections is the under-identification of Aboriginal and Torres Strait Islander people. Under-identification is a problem in mortality, hospital morbidity, and communicable disease data, particularly in some states and territories. As a result, data analysis using these sources has been limited to jurisdictions with adequate identification of Indigenous Australians, and this has been noted in relevant measures. Time-series analyses might also be affected by changes in the quality of Indigenous identification over time.

For current hospitalisation results (July 2013 – June 2015), all states and territories are considered as having data of sufficient quality to be included in the analyses. For short-term
trends (2004–05 to 2014–15), data from New South Wales, Victoria, Queensland, Western Australia, South Australia and the Northern Territory are used. For longer-term trends (1998–99 to 2014–15), data from only Queensland, Western Australia, South Australia and the Northern Territory are used.

Admission practices can differ across jurisdictions, which might affect comparisons between state and territories. Time series analyses for emergency department data might also be affected by changes in admission practices.

For both current and long-term mortality data (from 1998 onwards), New South Wales, Queensland, Western Australia, South Australia, and the Northern Territory are considered as having adequate levels of Indigenous identification to be included in the analyses.

Data on communicable diseases from the National Notifiable Disease Surveillance System have been found to have varying levels of completeness across diseases and jurisdictions. Results for each disease include only data from those jurisdictions considered to have adequate levels of Indigenous identification for that disease. Footnotes in tables and figures specify which jurisdictions have been included in each case.

The incompleteness of Indigenous identification in many administrative data sources results in an underestimate of the true rates for Indigenous Australians.

Surveys and other non-administrative data sources

Surveys that were used to obtain data for this report include Indigenous-specific surveys, such as the Australian Aboriginal and Torres Strait Islander Health Survey, and the National Aboriginal and Torres Strait Islander Social Survey. Data from the Census of Population and Housing have also been used.

Surveys are also subject to various data limitations, due to sampling and non-sampling errors, such as bias in responses. In many tables that are referred to in this report, estimates with large relative standard errors (which is a measure of the sampling variability) contain footnotes to indicate that they should be used with caution, or are considered too unreliable for general use.

For convenience, text and tables including data from the 2012–13 Australian Aboriginal and Torres Strait Islander Health Survey and the 2011–12 Australian Health Survey (which provides a non-Indigenous comparison) are referred to as being 2012–13 data.

Methods used for analysis

Comparison population

This report focuses on the health of Aboriginal and Torres Strait Islander people and how they are faring relative to other Australians. Wherever possible, results for Indigenous Australians are compared with those for non-Indigenous Australians—that is, people who identified as not being of Aboriginal or Torres Strait Islander origin.

This is not always possible, as some data sources do not allow for the separate identification of people who identified as not being of Aboriginal and/or Torres Strait Islander origin, and people for whom no Indigenous status information was available.

For other data sources, investigation has shown that the characteristics of records with unknown Indigenous status are more similar to those specified as not Indigenous than to those specified as Indigenous. So these may be grouped with the ‘not Indigenous’ records. In these cases, results for Indigenous Australians are compared with those for ‘other
Australians’, where the ‘other Australians’ group comprises non-Indigenous Australians and those of unknown Indigenous status. Text, tables and figures in this report clearly note whether ‘non-Indigenous Australians’ or ‘other Australians’ are the comparison population.

Population data

Population data are required when computing rates. The 2016 preliminary estimated resident population (ERP) is the latest available data that gives an estimate of the number of Aboriginal and Torres Strait Islander people in the population (ABS 2017). Because the 2016 ERP was released shortly before publication of this report, it was not available for use with the data. Therefore, unless otherwise noted, denominators used to calculate Indigenous Australian rates in this report are based on the ABS backcast Indigenous population estimates, and projections from the 2011 Census. Estimates of the non-Indigenous population for each year have been calculated by subtracting the Indigenous population estimates from the total Australian estimated resident population. These estimates have been used as denominators for both the ‘non-Indigenous’ and ‘other Australian’ rates.

The Census enumerated the Indigenous population from responses to a question on a person’s Indigenous status. The Indigenous estimated resident population for 2011 is computed using this enumerated figure, and adjusted for under-count based on results from the Post-Enumeration Survey, as well as for non-response to the Indigenous status question (ABS 2013a).

Estimates of the Indigenous estimated resident population at June 2011, based on the 2011 Census, are about 30 per cent as high as estimates of the 2006 Indigenous estimated resident population, based on the 2006 Census. This increase involved a 21% rise in the Census count (mostly at age groups under 19 years), and an increase in the measured under-count (influenced by improved Post-Enumeration Survey questions on Indigenous status). As a result, historical rates presented in this report will be different to those presented in previous Health Performance Framework reports.

Calculating rates

This report presents both crude and age-standardised rates.

A crude rate provides information on the number of events (for example, deaths of Indigenous Australians) relative to the population ‘at risk’ (for example, all Indigenous Australians). No age adjustments are made when calculating such a rate.

Crude rates might not always be suitable when making comparisons across time or between groups when differences by age structure exist (for example, the Indigenous population has a much younger age structure than the non-Indigenous population). In such situations, more meaningful comparisons can be made by using age-standardised rates, which take into account differences in age structures of the populations.

For this report, the Australian estimated resident population at 30 June 2001 (based on the 2001 Census) has been used as the standard population when deriving age-standardised rates. The same population was used for males and females to enable valid comparison of age-standardised rates between the sexes.

Two methods of age-standardisation can be used: direct and indirect. Unless otherwise noted (specifically, for hospital procedures and some perinatal data), direct age-standardisation has been used in this report.
Effects of rounding

Entries in columns and rows of tables might not add to the totals shown because of rounding. Derived values (such as proportions, rates, rate ratios and rate differences) are calculated using unrounded numbers. As a result, percentages cited in the text might not add to 100, due to rounding.

Comparing rates at a point in time

Comparison of rates for Indigenous and non-Indigenous (or other) Australians has been done by calculating rate differences and rate ratios.

A ‘rate difference’ measures the literal, or absolute, gap between 2 population rates; in this report, it is calculated as the rate for Indigenous Australians minus the rate for non-Indigenous Australians.

A ‘rate ratio’ measures the relative difference between populations by taking scale into account; in this report, it is calculated as the rate for Indigenous Australians divided by the rate for non-Indigenous Australians, and is interpreted as follows:

- A rate ratio of 1 indicates there is no difference between the rates.
- A rate ratio of less than 1 indicates the rate is lower in the Indigenous population.
- A rate ratio greater than 1 indicates the rate is higher in the Indigenous population.

A large rate ratio does not necessarily imply that an event has a large absolute impact. Events that are rare in the comparative population (the non-Indigenous population in this report) can produce large rate ratios, even if the prevalence of that event in the population of interest (the Indigenous population) is relatively low.

To determine whether the Indigenous and non-Indigenous rates are significantly different from each other, 95% confidence intervals are given around the rate difference or rate ratio. If these show that the rate difference is statistically significantly different from 0, or the rate ratio is significantly different from 1, then the rates are considered to be significantly different from each other at the p < 0.05 level (see Glossary).

A similar method has been used in tables that present data for subgroups of the Indigenous population (for example, smokers and non-smokers) to determine whether the results for those groups are significantly different from each other.

In tables, proportions, rates, rate ratios and rate differences that are statistically different from each other at the p < 0.05 level are marked with an asterisk (*). Footnotes in each table specify which results are being compared. Where results of significance testing differ between rate ratios and rate differences, results should be interpreted with caution.

Comparing rates over time

In cases where at least 4 data points are available, linear regression analysis has been used to calculate annual change and overall percentage change over the period, to determine whether there have been significant changes in the observed rates. Such analysis produces more powerful results, because the regression modelling has the advantage of jointly considering the information contained in the series of rates, rather than considering each time point separately.

Analysing the series of rates as a unit imposes stability and, consequently, the confidence band around the set of predicted values is narrower than when calculated around the rates separately. Footnotes in the tables indicate when linear regression analysis was used.
Linear regression uses the least squares method to calculate a straight line that best fits the data. The ‘slope’ of the line is an estimate of the average annual change in the data over the period—if the slope is statistically significantly greater than 0 then the data are said to have significantly risen over the period; if less than 0, then data have significantly fallen. The annual change estimates presented in this report represent the change each year in the units presented in the table (for example, number of deaths, or rate per 1,000), rather than the average annual percentage change often presented in other publications.

In contrast to Health Performance Framework publications before the 2014 edition, the overall percentage change estimates presented in this report are calculated using the start and end points of the fitted regression line, rather than the actual start and end data points. This overcomes the problem of variation from 1 data point to the next leading to highly variable percentage and annual change estimates. As a result, the time-trend results in this report should not be compared with Health Performance Framework publications prior to 2014.

Because percentage change is the change from the starting point (of the trend line), and the values of the starting points are generally different, the estimates presented for Indigenous and non-Indigenous Australians should not be compared with each other. In contrast, annual change estimates presented for Indigenous and non-Indigenous Australians can be compared.

Both small numbers and variability in the data from year to year can make it difficult to detect significant changes over time, and can have an impact on any conclusions reached from a trend analysis. This is a particular problem when analysing trends for small populations, such as the Indigenous population in the smaller jurisdictions. Care should be taken when assessing apparent changes over time, particularly those involving small numbers and a small number of data points.

Time-series analysis of rate ratios has not been done in the 2017 Health Performance Framework, as the accuracy of this testing might be low. As rate ratios often do not rise or fall in a linear manner, applying linear regression to rate ratios might not accurately reflect the change over time.

Significance testing

Annual change and per cent change were only calculated for a series of 4 or more data points. The 95% confidence intervals (CIs) for the standard error of the slope estimate (annual change) based on linear regression are used to determine whether the apparent increases or decreases in the data are statistically significant at the p < 0.05 level. The formula used to calculate the CIs for the standard error of the slope estimate is:

$$95\%\ CI\ (x) = x \pm t^{*} (n-2) \times SE\ (x)$$

where x is the annual change (slope estimate), t* (n–2) is the 97.5th quintile of the tn–2 distribution. If the upper and lower 95% confidence intervals do not include zero, then it can be concluded that there is statistical evidence of an increasing or decreasing trend in the data over the study period. Significant changes are denoted with a * against the annual change statistics included in relevant tables.

Testing rate differences and rate ratios

If the 95% CIs of the difference in rates do not include zero, then it can be concluded that there is statistical evidence of a difference in rates. If the 95% CIs of the rate ratio do not include 1, then it can be concluded that there is statistical evidence of a difference in the rates contributing to the rate ratio. Tables include a * next to the rate ratio and rate difference to indicate that rates for the Indigenous and non-Indigenous populations are statistically different from each other at the p < 0.05 level (based on 95% CIs). Where results of
significance testing differed between rate ratios and rate differences, caution should be exercised in the interpretation of the tests.

**Remoteness areas**

Remoteness is an important factor in understanding the health of Indigenous Australians. Remoteness areas in this report are classified using the Australian Statistical Geography Standard Remoteness Structure, based on the Accessibility/Remoteness Index of Australia, which measures the remoteness of a point based on the physical road distance to the nearest urban centre (ABS 2013b).

The ABS classifications for remoteness have recently been subject to revision. Rates for 2011 remoteness areas are calculated using 2011 Census estimated resident populations, so should not be compared with rates calculated using estimated resident populations based on previous censuses.

**Measuring the gap**

Throughout this report, the term 'the gap' is used to refer to the rate difference. For trend analyses, references to the widening or narrowing of the gap refer to changes in the rate difference over time.

**Reading about diagnoses and causes of death**

This report presents information on hospitalisations and deaths from specific diseases and injuries. This information usually refers to hospitalisations with a principal diagnosis of a particular disease or injury, or deaths with an underlying cause of the disease or external cause of injury (see Glossary).

For ease of reading, in this report, the phrases ‘hospitalisations for’ or ‘hospitalised due to’ mean ‘hospitalisations with a principal diagnosis of’. Similarly, the phrase ‘deaths due to’ means ‘deaths with an underlying cause of’.

In death records, coding rules indicate that the event causing the injury or poisoning leading to death should be recorded as the underlying cause of death. These are referred to as ‘external causes’.

For ease of reading, the phrase ‘deaths due to injury and poisoning’ is used in this report, to mean ‘deaths with an underlying cause of an external cause of injury or poisoning’.
Data improvement activities

Jurisdictions, in liaison with the AIHW and the ABS have been actively engaged and committed to a range of activities to improve the quality of Aboriginal and Torres Strait Islander data in health data collections. These activities were funded by the Council of Australian Governments (COAG) and the Australian Government with a total budget of $46.4 million over 4 years to June 2013 under the National Indigenous Reform Agreement. The activities cover the key data sets required for Indigenous reporting under the National Indigenous Reform Agreement, including mortality data, morbidity data, perinatal data, and population estimates.

Major data development activities done or in progress by the AIHW are described in this section. Those achieved by the ABS include:

- improvements to the Census Indigenous enumeration procedures and expansion of the Census Post-Enumeration Survey
- timing of the National Aboriginal and Torres Strait Islander Social Survey and Australian Aboriginal and Torres Strait Islander Health Survey scheduled at 6-yearly cycles to provide 3-yearly estimates for key statistics collected in both surveys
- 2011 Census records linked with death registration records to assess the level of Indigenous identification.

A variety of data improvement activities have also been done or are in progress throughout the states and territories. Further detail on these activities is available in the Health Performance Framework policy report technical appendix (AHMAC 2017).

Perinatal National Minimum Data Set

AIHW is working with the states and territories to develop an improved Perinatal National Minimum Data Set (NMDS), with improvements including the following:

- Nationally consistent data items on smoking during the first 20 weeks and after the first 20 weeks of pregnancy until the birth, were included in the Perinatal NMDS from 1 July 2010.
- A data item for the Indigenous status of the baby was added to the Perinatal NMDS from 1 July 2012.
- A data item on the estimated duration of pregnancy at the first visit for antenatal care was added to the Perinatal NMDS from 1 July 2010.
- A data item on the number of antenatal visits was included in the Perinatal NMDS from 1 July 2013.
- New voluntary data items have been added to the Perinatal Data Set Specifications (birth year), including:
  - reasons for caesarean section (2014–15)
  - maternal height and weight (2014–15)
  - diabetes, diabetes mellitus during pregnancy, and type of diabetes (2014–15)
  - hypertensive disorder during pregnancy (2014–15)
  - primary postpartum haemorrhage, blood transfusion for postpartum haemorrhage, and estimated postpartum haemorrhage blood loss (2014–15)
  - indication for induction of labour (2015–16)
• The AIHW is currently consulting jurisdictions about including and developing psychosocial data items for screening during antenatal visits, which might include information about alcohol use during pregnancy, antenatal anxiety and depression, and illicit substance use in pregnancy.

• The Maternity Model of Care Data Set Specification was approved by National Health Information Standards and Statistics Committee, and added to the National Health Data Dictionary in May 2015. The AIHW has started collecting maternity models of care data from 91 registered users from participating maternity services in Australia.

Improving Indigenous identification in data sets

The AIHW released national best-practice guidelines for collecting Indigenous status in health data sets in April 2010. The AIHW provides continuing support for better Indigenous identification through its National Indigenous Data Improvement Support Centre’s helpdesk, which gives advice and assistance to health providers on issues relating to collecting and recording Indigenous status. The centre also supports better Indigenous data collection, by providing resources and training materials.

The ABS continues to conduct various engagement and education activities, liaise with government departments about best practice in Indigenous data collections, and conduct data linkage programs to assess and improve Indigenous identification status.

The ABS also has in place an Indigenous Community Engagement Strategy to improve the collection and dissemination of statistics, in partnership with Aboriginal and Torres Strait Islander communities. Through the use of Indigenous Engagement Managers in ABS offices across Australia, the ABS is building relationships with communities to improve the quality and relevance of Aboriginal and Torres Strait Islander statistics.

More information on ABS key directions in Aboriginal and Torres Strait Islander statistics can be obtained in the ABS’s 2012–13 annual report (ABS 2013c).

National best-practice guidelines for data linkage activities relating to Aboriginal and Torres Strait Islander people

The AIHW and ABS in partnership with jurisdictions, developed national best-practice guidelines for linking data relating to Indigenous people. The guidelines for linking Indigenous data covered linkage methods and protocols, privacy protocols, quality standards, and procedures. The National Best Practice Guidelines for Data Linkage Activities Relating to Aboriginal and Torres Strait Islander People were released on 9 July 2012, with 2 attachments released on 14 June 2013. The attachments review the current and recent body of data linkage activities relating to Aboriginal and Torres Strait Islander people, along with a thematic listing of these activities. In describing and comparing data linkage practices to date, these documents provide an evidence base for the national data linkage guidelines.

Improving estimates of Indigenous under-identification in key data sets

The AIHW has published reports on the assessment of the quality of Indigenous identification in labour force data collections, community services data collections, the National Cancer Registry, the National Diabetes Register, the national Key Performance Indicator data collection and in hospital separations data.
Improving estimates of Indigenous mortality

The AIHW’s Enhanced Mortality Database project aimed to improve information on Indigenous status on the registered deaths data set, by linking it to several additional data sources that contain information on deaths and Indigenous identification—namely admitted hospital records, perinatal records, and residential aged care data. This enables more accurate estimates of Aboriginal and Torres Strait Islander mortality and life expectancy.

Implementation Plan for the National Aboriginal and Torres Strait Islander Health Plan

Following on from the COAG targets, the Australian Government worked with Aboriginal and Torres Strait Islander people to produce the National Aboriginal and Torres Strait Islander Health Plan 2013–2023. This sets out a 10-year plan for the direction of Indigenous health policy and provides a long-term, evidence-based policy framework to close the gap in Indigenous disadvantage. The vision outlined in the Health Plan around health system effectiveness is that the Australian health system delivers primary health care that is evidence-based, culturally safe, high quality, responsive and accessible to all Aboriginal and Torres Strait Islander people (DoH 2013).

An Implementation Plan sits alongside the Health Plan, detailing the actions to be taken by the Australian Government and other key stakeholders to implement the Health Plan (DoH 2015). It identifies 20 goals to support the achievement of the COAG targets around the effectiveness of the health system and priorities across the life course, from maternal health and parenting, childhood health and development, adolescent and youth health, healthy adults and healthy ageing. A technical companion document to the Implementation Plan outlines these goals and how they will be measured (AIHW 2015a).

The second stage of the Implementation Plan will be released in 2018 and will further develop actions and goals in the domain of social and cultural determinants of health and health system effectiveness. It will also seek to increase engagement between Australian Government agencies, state, territory and local governments, the Aboriginal community-controlled health sector, the non-government sector and the corporate/private sector (DoH 2017).

Progress on achieving the Implementation Plan goals will be reported every two years in line with the release of the Aboriginal and Torres Strait Islander Health Performance Framework. The findings will be incorporated into the Department of Health’s Annual Report and will inform the Prime Minister’s annual Closing the Gap report. Progress on the goals will also be publicly reported on the DoH and AIHW websites from mid-2017 (DoH 2015).

Enhanced Perinatal National Minimum Data Set

The AIHW Linked Perinatal, Births, Deaths Data set Project aims to create a national, ongoing, linked perinatal, birth and death data set to obtain more accurate estimates of Indigenous infant and child mortality, and to analyse the factors affecting infant and child health outcomes in Australia. Infant and child death rates are important markers of population health.
At the national level, combined data show significant differences in infant and child death rates within Australia by factors such as Indigenous status, sociodemographics, and maternal health status. But these factors are not able to be analysed simultaneously, as they are dispersed across various data sources.

An initial data set is being created by linking unit record level data across jurisdictions from perinatal data collections, birth records, and death records. It covers all births from 2003 to 2010, and deaths within this birth cohort that occurred up to age 5.

National linkage, including all relevant births and all deaths occurring up to mid-2016 was completed in late 2016, and the resulting data are now being analysed. The first report from the project, which uses unlinked perinatal data to look at factors associated with poor birth outcomes, will be published by the AIHW in 2017.

Including Indigenous status in pathology data

The AIHW’s 2013 report *The inclusion of Indigenous status on pathology request forms* (AIHW 2013) outlines work towards including Indigenous status on pathology request forms to improve Indigenous identification in national cancer, communicable disease and cervical screening registries.

Other relevant activities

Closing the Gap Clearinghouse

The AIHW in collaboration with the Australian Institute of Family Studies delivered the Closing the Gap Clearinghouse. The Clearinghouse is an online collection of research and evaluation evidence on what works to overcome Indigenous disadvantage. It focuses on 7 subject areas: early childhood, schooling, health, economic participation, healthy homes, safe communities, and governance and leadership.

The Clearinghouse supports policymakers and service providers involved in overcoming Indigenous disadvantage, by providing access to and synthesising the evidence on particular topics. As the contract for the Clearinghouse ended in June 2014, no new material is being added, though all resources and publications already published continue to be available.

National Prisoner Health Data Collection

The National Prisoner Health Data Collection was first conducted in 2009, based on a set of indicators aligned to the National Health Performance Framework, and designed to monitor the health of prisoners. Subsequent data collections were held in 2010, 2012 and 2015.

The collection provides information on the health of people entering prison (prison entrants), health conditions managed at prison clinics, medications administered at the clinics, the health of people about to be released from prison (prison discharges), and operations of the clinics. Major reports relating to each data collection have been released by the AIHW, supplemented by smaller bulletins focused on topics such as mental health. All of these reports include analysis of the health of Aboriginal and Torres Strait Islander prisoners.

Mapping of health services and need

The AIHW has completed a series of projects looking at the geographic distribution of health services, and mapping against potential need for these services among Aboriginal and Torres Strait Islander people.
The first project involved developing an area-based index that measures access to general practitioners (GPs), relative to the need for primary health care for both the Indigenous and non-Indigenous populations. Access to primary health care relative to need for Indigenous Australians (AIHW 2014a) shows that, on average, for both population groups, access to GPs and access to GPs relative to need reduces with increasing remoteness, but that the effect appears to be greater for the Indigenous population.

The 2nd project, reported in Spatial variation in Aboriginal and Torres Strait Islander people’s access to primary health care (AIHW 2015b), aimed to identify areas with critical service gaps for the Indigenous population in relation to their access to primary health care. Areas with potential service gaps were defined as Statistical Areas Level 2 with no Indigenous-specific primary health-care service located within 1 hour's drive, and with poor access to GP services in general.

The 3rd report, Spatial distribution of the supply of the clinical health workforce 2014: relationship to the distribution of the Indigenous population (AIHW 2016a), uses a new measure developed by the AIHW—the Geographically-adjusted Index of Relative Supply—to look at the geographic supply of the clinical health workforce in 7 key professions with particular relevance to Indigenous Australians. These professions were general practitioners, nurses, midwives, pharmacists, dentists, psychologists, and optometrists. Areas with lower scores under the index are more likely to face workforce supply challenges than those with higher scores.

The Geographically-adjusted Index of Relative Supply is an important resource for policy discussions on improving the supply of health services.

The 4th project is looking at the distribution of maternal and child health services in relation to the geographic distribution of Indigenous women of childbearing age and Indigenous children. The aim of this work is to find gaps and look at whether the supply of these services is associated with relevant health outcomes (for example, low birthweight, smoking during pregnancy, antenatal care use) at low geographic levels. This project is expected to be published in 2017.

**Closing the Gap initiatives**

With the 10th anniversary of Closing the Gap approaching in 2018, the COAG has agreed to work together, and with Indigenous Australians, to refresh the Closing the Gap agenda.

The AIHW has contributed to this work, and investigated when the Closing the Gap health initiatives are likely to have an impact on the Indigenous child mortality target. This work involved looking at the main drivers affecting the child mortality target, interventions that have been shown to be effective in reducing risk factors and child mortality, and time lags between program implementation, expected reductions in child mortality, and the availability of data to measure the outcomes that have been achieved.

The report, Timing impact assessment for COAG Closing the Gap targets: child mortality (AIHW 2014b), suggests that the full effect of the COAG maternal and child health initiatives might not be evident for many years.

**Indigenous burden of disease**

The AIHW received funding from the Australian Government Department of Health and the previous Australian National Preventive Health Agency to revise and update Australia’s burden of disease estimates for the total Australian population and the Aboriginal and Torres Strait Islander population.
This work, which was last updated in 2007 using 2003 data, builds on the AIHW’s previous burden of disease studies and existing disease monitoring work. It aims to identify the extent and distribution of health problems in Australia, and quantify the contribution of key health risks.

Estimates of the fatal and non-fatal burden of disease for Indigenous Australians are presented in Australian Burden of Disease Study: fatal burden of disease in Aboriginal and Torres Strait Islander people 2011 (AIHW 2016b). That report also includes estimates of the gap in disease burden between Indigenous and non-Indigenous Australians. The disease groups causing the most burden among Indigenous Australians in 2011 were mental and substance use disorders, injuries, cardiovascular diseases, cancer and respiratory diseases. Indigenous Australians experienced a burden of disease that was 2.3 times the rate of non-Indigenous Australians. More than one-third of the overall disease burden experienced by Indigenous Australians could be prevented by removing exposure to risk factors such as tobacco and alcohol use, high body mass, physical inactivity and high blood pressure.

**New South Wales data improvement activities**

Under the National Indigenous Reform Agreement, New South Wales has committed to data quality improvement activities that will improve the accuracy and reliability of closing the gap reporting.

NSW Health has adopted the standard ABS Indigenous status question and recording categories, and has issued this revision to the NSW Health system to mandate that the standard question is incorporated into all data collection forms and information systems for key data sets.

NSW Health has employed a project officer Aboriginal data quality for the Health Systems Information and Performance Reporting Branch. The position supports the development of policies, protocols and strategies to enhance the quality of health data pertaining to the Aboriginal population of NSW. The position is responsible for routine data profiling of data collections to identify data quality issues. It is also responsible for supporting the state-wide implementation of data quality processes and programs and will support the development of data collection standards.

Respecting the Difference: An Aboriginal Cultural Training Framework for NSW Health outlines a mandatory cultural training framework for all staff working in health, and includes information on collecting Indigenous status information.

NSW Health has completed a project Improved Reporting of Aboriginal and Torres Strait Islander people on population datasets using record linkage. The project:

- developed methods for improving reporting of Aboriginal and Torres Strait Islander people on population datasets using record linkage
- described the improvements in reporting achieved by record linkage
- explored the impact of any changes in reporting due to record linkage on a selection of indicators of health status and health service utilisation.

The method is being used to monitor the level of reporting of Aboriginal people on selected administrative datasets. Information on the quality of reporting of Aboriginal people is available on the Health Stats NSW website for public and private hospital morbidity data, the Emergency Department Data Collection and the Perinatal Data Collection.

Local health districts are implementing initiatives to raise awareness about the importance of identifying as an Aboriginal person. The programs are designed and implemented locally.
For example, the Mid-North Coast Local Health District has implemented the Closing the Gap—Innovation in Emergency Departments project that aims to create a better patient journey for Aboriginal people using the hospital and to reduce the number of ‘did not wait’ patients. It is focused on the emergency department environment, training of staff on identification, getting clinicians involved in cultural awareness programs, and addressing barriers that prevent people from waiting. Various strategies are included for example, amusements for children, information on why identification is important, resources, posters including a triage poster, DVD, and cultural awareness information. The district has also established a new alert system, where the Aboriginal liaison officer receives a message that an Aboriginal patient is in the emergency department. The program has shown a reduction of ‘did not wait’ patients in the emergency department by about 50%.
Tier 1—Health status and outcomes
1.01 Low birthweight

Why it is important

This measure reports on low birthweight among live born babies of Indigenous mothers. Low birthweight (newborns weighing <2,500 grams) is associated with being born early (pre-term) or being small for gestational age, which indicates possible growth restriction within the uterus. Low birthweight infants are at a greater risk of dying during their first year of life; are prone to ill-health in childhood and the development of chronic diseases as adults, including cardiovascular disease, high blood pressure, kidney disease and type 2 diabetes (Arnold et al. 2015; Hoy & Nicol 2010; Luyckx et al. 2013; OECD 2011; Scott 2014; White et al. 2010; Zhang et al. 2013).

Key findings

**Overall:** In New South Wales in 2014, and considering live born babies only, low birthweight was almost twice as common among babies born to Indigenous mothers (10.9%) as those born to non-Indigenous mothers (5.9%). Low birthweight is associated with multiple births (AIHW 2016c). After excluding multiple births, the proportions were 9.4% and 4.5%, respectively.

Nationally, low birthweight was also almost twice as common among all live born babies born to Indigenous mothers (11.8%) as those born to non-Indigenous mothers (6.2%). After excluding multiple births, the proportions were 10.5% and 4.7%, respectively (Table 1.01.1, Figure 1.01.1).

**Mean birthweight:** Nationally, the mean birthweight for infants born to Indigenous mothers in 2014 was less than babies of non-Indigenous mothers, 3,217 grams compared with 3,356 grams (Table 1.01.5).

**Trend over time:** The numbers of multiple births rose (although rates fell) between 2004 and 2014. This is due to factors such as increased use of fertility treatments and delays in child bearing that result in higher proportions of older mothers (AIHW 2015c). As a result, multiple births are often excluded from statistics that present trends in birthweight.

In New South Wales between 2000 and 2014, the low birthweight rate for singleton babies born to Indigenous mothers fell by 19.5%, from 11.0% in 2000 to 9.4% in 2014.

There were 6 jurisdictions that had data of adequate quality to report long-term trends. In NSW, Qld, Vic, WA, SA and the NT combined, the low birthweight rate for singleton babies born to Indigenous mothers declined by 12.6% between 2000 and 2014, from 11.7% to 10.5% (Table 1.01.3, Figure 1.01.2).

**Age of Indigenous mothers:** Nationally, in 2014, the proportion of low birthweight singleton births was highest for Indigenous mothers aged 35 and over (12.5%). For non-Indigenous mothers it was highest for those aged less than 20 (7.6%) (Table 1.01.7, Figure 1.01.3).
Figure 1.01.1: Proportion of low birthweight, all live born babies, by Indigenous status of mother, New South Wales and Australia, 2014

Figure 1.01.2: Proportion of low birthweight live born singleton babies, by Indigenous status of mother, New South Wales and NSW, Vic, Qld, WA, SA and NT combined, 2000–2014

Figure 1.01.3: Proportion of low birthweight live born singleton babies, by age group (years) and Indigenous status of the mother, Australia, 2014

**1.02 Top reasons for hospitalisation**

**Why it is important**

This measure reports on the leading causes of hospitalisation. Rates indicate the occurrence in a population of serious illnesses and conditions that require hospitalisation, and use of hospitals by people with such conditions. Rates are based on the number of hospital episodes rather than the number of individual people who are hospitalised. Rates do not necessarily reflect the level of occurrence of an illness in the population (AHMAC 2017).

**Key findings**

**Overall:** In New South Wales between July 2013 and June 2015, the age-standardised hospitalisation rate (excluding dialysis) for Indigenous Australians was 376 per 1,000. This was 1.2 times the rate for non-Indigenous Australians.

Nationally, the age-standardised hospitalisation rate (excluding dialysis) for Indigenous Australians was 417 per 1,000. This was 1.2 times the rate for non-Indigenous Australians. After adjusting for Indigenous under-identification, the hospitalisation rate for Indigenous Australians was 1.3 times the rate for non-Indigenous Australians (Table 1.02.1).

**Top reasons for hospitalisation:** In New South Wales, the age-standardised rate for care involving dialysis was the leading reason for hospitalisation for Indigenous Australians (197 per 1,000). The next most common reasons were pregnancy and childbirth (57 per 1,000), and injury and poisoning (38 per 1,000).

Nationally, the age-standardised rate for care involving dialysis was the most common reason for hospitalisation (472 per 1,000), followed by pregnancy and childbirth (59 per 1,000), and injury and poisoning (47 per 1,000) (Table 1.02.5 NSW, Figure 1.02.1).

**Trend over time:** In New South Wales between 2004–05 and 2014–15, the age-standardised hospitalisation rate (excluding dialysis) rose at a faster rate for Indigenous Australians (by 58%—from 245 to 382 per 1,000) than non-Indigenous Australians (by 16% from 274 to 320 per 1,000). Until 2009–10, the hospitalisation rate for Indigenous Australians was lower than for non-Indigenous Australians, but this changed in 2010–11 when the rate for Indigenous Australians became higher (by 3 per 1,000), and continued to rise, resulting in a rate difference of 62 per 1,000 in 2014–15.

Between 2004–05 and 2014–15, in NSW, Qld, Vic, WA, SA and the NT combined, the age-standardised rate rose by 37% for Indigenous Australians, from 317 to 433 per 1,000. The rate for non-Indigenous Australians increased by 14% over this time (from 294 to 339 per 1,000) (Table 1.02.4 NSW, Figure 1.02.2).

**Age group:** In New South Wales between July 2013 and June 2015, the hospitalisation rate was higher for Indigenous Australians than non-Indigenous Australians for all age groups except 65 and over. The largest difference was for those aged 15–24, where the rate for Indigenous Australians was 1.5 times the rate for non-Indigenous Australians.

Nationally, for all age groups under 65, the rate was higher for Indigenous Australians than non-Indigenous Australians. The largest difference was for those aged 45–54, where the rate for Indigenous Australians was 1.6 times the rate for non-Indigenous Australians (Table 1.02.2 NSW, Figure 1.02.3).

Aboriginal and Torres Strait Islander Health Performance Framework 2017: New South Wales  23
1.03 Injury and poisoning

Why it is important

This measure reports on injury and poisoning. Injury and poisoning can cause long-term disability and disadvantage, including reduced opportunities for education and employment, communication impairment and burden on caregivers (Stephens et al. 2014).

Key findings

Overall: In New South Wales between July 2013 and June 2015, the age-standardised hospitalisation rate for injury and poisoning was 38 per 1,000 for Indigenous Australians, 1.5 times the rate for non-Indigenous Australians 25 per 1,000.

Nationally, the age-standardised hospitalisation rate for injury and poisoning was 47 per 1,000 for Indigenous Australians, 1.8 times the rate for non-Indigenous Australians (25 per 1,000) (Table 1.03.3, Figure 1.03.1).

Age group: In New South Wales between July 2013 and June 2015, the rate of hospitalisation for injury and poisoning was highest for those aged 65 and over, for both Indigenous Australians (55 per 1,000) and non-Indigenous Australians (60 per 1,000).

Nationally, the rate of hospitalisation for injury and poisoning was highest for Indigenous Australians aged 35–44 (60 per 1,000). The highest rate for non-Indigenous Australians was for those aged 65 and over, 58 per 1,000 (Table 1.03.2 NSW, Figure 1.03.2).

Leading cause: In New South Wales between July 2013 and June 2015, falls were the leading cause of injury and poisoning requiring hospitalisation for Indigenous Australians (23%).

Nationally, assault was the highest cause of injury and poisoning requiring hospitalisation for Indigenous Australians (20.1%), followed by falls (19.7%) (Table 1.03.7 NSW).

Injuries in previous 4 weeks: In New South Wales in 2012–13, 19% of Indigenous Australians surveyed reported having an injury in the previous 4 weeks. The proportion was higher in Non-remote (20%) than in Remote areas (16%).

Nationally, 19% of Indigenous Australians surveyed reported having an injury in the previous 4 weeks. The proportion was higher in Non-remote areas (20%) than in Remote areas (14%) (Table 1.03.10).

Trend over time: In New South Wales, the age-standardised rate of hospitalisation for injury and poisoning for Indigenous Australians rose by 63%, from 24 per 1,000 in 2004–05 to 38 per 1,000 in 2014–15. The gap between Indigenous and non-Indigenous Australians widened from 2 per 1,000 in 2004–05 to 13 per 1,000 in 2014–15, an annual rate increase of 1.2 per 1,000.

In NSW, Vic, Qld, WA, SA and the NT combined, the age-standardised rate for Indigenous Australians rose by 38%, from 36 per 1,000 in 2004–05 to 48 per 1,000 in 2014–15. The gap between Indigenous and non-Indigenous Australians widened by 79% from 14 per 1,000 in 2004–05 to 23 per 1,000 in 2014–15, a rate increase of 1.0 per 1,000 per year (Table 1.03.5 NSW, Figure 1.03.3).

1.04 Respiratory diseases

Why it is important

This measure reports on deaths, hospitalisation and prevalence of respiratory diseases. Indigenous people have higher mortality and morbidity from respiratory diseases such as asthma, chronic obstructive pulmonary disease (including bronchitis and emphysema), pneumonia and invasive pneumococcal disease than other Australians (AHMAC 2017).

Key findings

**Overall:** In New South Wales in 2012–13, 40% of Indigenous Australians reported having respiratory diseases that had lasted, or was likely to last for 6 months or more. The proportions were similar for those living in Remote (41%) and Non-remote areas (40%). Nationally in 2012–13, 31% of Indigenous Australians reported having respiratory diseases that had lasted, or was likely to last 6 months or more. A higher proportion of Indigenous Australians living in Non-remote areas (35%) reported having respiratory diseases than those living in Remote areas (18%) (Table 1.04.2, Figure 1.04.1).

**Deaths:** In New South Wales in 2011–15, 364 Indigenous Australians died from respiratory diseases, an age-standardised rate of 90 deaths per 100,000. The rate for non-Indigenous Australians was 51 deaths per 100,000.

In NSW, Qld, WA, SA and the NT combined, the age-standardised death rate for Indigenous Australians for respiratory diseases was 101 per 100,000, compared with 50 per 100,000 for non-Indigenous Australians (Table 1.23.2, Figure 1.04.2).

**Hospitalisation:** In New South Wales between July 2013 and June 2015, the age-standardised hospitalisation rate for Indigenous Australians for respiratory diseases was twice the rate for non-Indigenous Australians (34 and 17 per 1,000, respectively) (Table 1.04.7). Rates for Indigenous Australians were highest in the youngest and oldest age groups: 73 per 1,000 for those aged 0–4; and 102 per 1,000 for those aged 65 and over (Table 1.04.8 NSW).

Nationally, the age-standardised hospitalisation rate for Indigenous Australians for respiratory diseases was 39 per 1,000, 2.4 times the rate for non-Indigenous Australians (17 per 1,000) (Table 1.04.7). Hospitalisation rates for Indigenous Australians for respiratory diseases were similar to New South Wales in all age groups 78 per 1,000 for those aged 0–4, and 101 per 1,000 for those aged 65 and over (Table 1.04.8 NSW).

**Trend over time:** In New South Wales, the age-standardised hospitalisation rate for respiratory diseases for Indigenous Australians rose from 24 per 1,000 in 2004–05 to 35 per 1,000 in 2014–15, a 40% rise. The rate for non-Indigenous Australians remained stable (about 16 per 1,000). The rate difference between Indigenous and non-Indigenous Australians rose by 95% (from 8 to 17 per 1,000).

In NSW, Vic, Qld, WA, SA and the NT combined, the age-standardised rate for Indigenous Australians rose by 18% (from 36 to 42 per 1,000), and the rate for non-Indigenous Australians rose by 8% (from 16 to 17 per 1,000). The rate difference between Indigenous and non-Indigenous Australians rose by 26% (from 20 to 25 per 1,000) (Table 1.04.11 NSW, Figure 1.04.3).
Figure 1.04.1: Rate of Indigenous Australians reporting respiratory diseases, by remoteness area, New South Wales and Australia, 2012–13

Figure 1.04.2: Age-standardised death rate from respiratory diseases, by Indigenous status, New South Wales and NSW, Qld, WA, SA and NT combined, 2011–2015

Figure 1.04.3: Age-standardised hospitalisation rate for respiratory diseases, by Indigenous status, New South Wales and NSW, Vic, Qld, WA, SA and NT combined, 2004–05 to 2014–15

1.05 Circulatory diseases

**Why it is important**

This measure reports on prevalence, incidence, deaths and hospitalisations caused by circulatory diseases. Circulatory diseases are a major cause of morbidity and mortality for Indigenous Australians. They are more common among Indigenous than non-Indigenous Australians and tend to occur at younger ages (AIHW 2015d; Bradshaw et al. 2011; Brown 2012; Katzenellenbogen et al. 2014).

**Key findings**

**Overall:** In New South Wales in 2012–13, 13% of Indigenous Australians reported having a heart/circulatory condition (Table 1.05.1). The age-standardised rate for Indigenous Australians with heart/circulatory conditions (20%) was higher than for non-Indigenous Australians (17%). The rate was higher in Remote (33%) than in Non-remote areas (19%).

Nationally, 13% of Indigenous Australians had a heart/circulatory condition (Table 1.05.1). The age-standardised rate for Indigenous Australians was higher than for non-Indigenous Australians (20% compared with 16%). The rate was also higher in Remote than Non-remote areas (26% compared with 18%) (Table 1.05.2, Figure 1.05.1).

**Hospitalisation:** In New South Wales between July 2013 and June 2015, the age-standardised rate for hospitalisation for circulatory diseases for Indigenous Australians was 1.6 times the rate for non-Indigenous Australians (28 compared with 18 per 1,000). The rate of hospitalisation was higher for Indigenous males (32 per 1,000) than Indigenous females (25 per 1,000).

Nationally, the age-standardised rate for hospitalisation for circulatory diseases for Indigenous Australians was 1.8 times the rate for non-Indigenous Australians (32 compared with 18 per 1,000). The rate of hospitalisation was higher for Indigenous males (35 per 1,000) than for Indigenous females (29 per 1,000) (Table 1.05.7).

**Mortality:** In New South Wales between 2011 and 2015, circulatory diseases were the leading cause of death in New South Wales. The age-standardised death rate caused by circulatory diseases was higher for Indigenous Australians than for non-Indigenous Australians (233 compared with 178 per 100,000).

In NSW, Qld, WA, SA and the NT combined, circulatory diseases were the leading cause of death. The age-standardised death rate for circulatory diseases was higher for Indigenous Australians than for non-Indigenous Australians (271 compared with 173 per 100,000) (Table 1.23.2, Figure 1.05.2).

**Trend over time:** In New South Wales between 2004–05 and 2014–15, the age-standardised rate of hospitalisation for Indigenous Australians for circulatory diseases rose by 29% (from 22 to 28 per 1,000). For non-Indigenous Australians the rate fell by 16% (from 21 to 17 per 1,000). For mortality time trends, see Measure 1.23.

In NSW, Vic, Qld, WA, SA and the NT combined, the age-standardised rate of hospitalisation for Indigenous Australians for circulatory diseases rose by 17% (from 28 in 2004–05 to 33 per 1,000 in 2014–15). For non-Indigenous Australians it fell by 12% (from 21 to 18 per 1,000) (Table 1.05.11 NSW, Figure 1.05.3).

Figure 1.05.2: Age-standardised death rate from circulatory diseases, by Indigenous status, New South Wales and NSW, Qld, WA, SA and NT combined, 2011–2015

Figure 1.05.3: Age-standardised hospitalisation rate for circulatory diseases, by Indigenous status, New South Wales and NSW, Vic, Qld, WA, SA and NT combined, 2004–05 to 2014–15

1.06 Acute rheumatic fever and rheumatic heart disease

Why it is important

This measure reports on the incidence and prevalence of acute rheumatic fever (ARF) and rheumatic heart disease (RHD). ARF is a disease caused by an autoimmune reaction to an infection with the bacterium group A streptococcus (GAS). ARF is a short illness, but can result in permanent damage to the heart (RHD). ARF and RHD are associated with environmental factors such as poverty and poor living conditions. ARF and RHD are now rare diseases in populations with good living conditions and easy access to quality medical care (He et al. 2016). Indigenous Australians remain at risk of ARF/RHD because of socioeconomic disadvantage and barriers to accessing health care (AHMAC 2017).

Key findings

Acute rheumatic fever and rheumatic heart disease: Data from the New South Wales rheumatic heart disease register were not available at the time of collation.

In the NT, WA, Qld and SA combined, in 2011–2015 (note that South Australian data is for 2013 to 2015 only), there were 1,204 new or recurrent cases of acute rheumatic fever. Of these, 94% were Indigenous Australians, a rate of 0.6 per 1,000 (Table 1.06.1). In Qld, WA and the NT combined, 55% of cases occurred in children aged 0–14, and 26% in those aged 15–24 (Table 1.06.2).

Hospitalisation: In New South Wales between July 2013 and June 2015, the age-standardised rate of hospitalisation for Indigenous Australians for acute rheumatic fever or rheumatic heart disease was twice the rate for non-Indigenous Australians (0.2 per 1,000 compared with 0.1 per 1,000).

Nationally, the age-standardised rate of hospitalisation for Indigenous Australians for acute rheumatic fever or rheumatic heart disease (0.7 per 1,000) was 7 times the rate for non-Indigenous Australians (0.1 per 1,000) (Table 1.06.17, Figure 1.06.1).

Hospitalisation by age: Numbers and rates of hospitalisation are not published by jurisdiction and age, due to the small numbers involved.

Nationally, between July 2013 and June 2015, the highest proportion of hospitalisations for Indigenous Australians for acute rheumatic fever or rheumatic heart disease was for those aged 10–14, at 1.6 per 1,000. For non-Indigenous Australians, the highest hospitalisation rate was for those aged 65 and over, at 0.5 per 1,000 (Table 1.06.18, Figure 1.06.2).

Mortality: Numbers and rates of deaths due to rheumatic heart disease are not available by jurisdiction due to small numbers.

In 2011–2015 in NSW, Qld, WA, SA and the NT combined, 108 Indigenous Australians died due to rheumatic heart disease, which accounted for 3.4% of deaths due to circulatory diseases. This was an age-standardised rate of 6.4 per 100,000, 4.7 times the rate for non-Indigenous Australians (1.4 per 100,000). Age-standardised death rates for Indigenous males (4.5 per 100,000) were lower than rates for Indigenous females (8.1 per 100,000) (Table 1.23.8, Figure 1.06.3).

The number of deaths of Indigenous Australians due to rheumatic heart disease increased with age, and the majority (81%) occurred in those aged 35 and older (Table 1.23.9).

1.07 High blood pressure

Why it is important

This measure reports on the prevalence (self-reported and measured) of high blood pressure (also referred to as hypertension). High blood pressure is a major risk factor for stroke, coronary heart disease, heart failure, kidney disease, deteriorating vision and peripheral vascular disease (which leads to leg ulcers and gangrene). Reducing the prevalence of high blood pressure is one of the most important means of reducing serious circulatory diseases, which are the leading cause of death among Indigenous Australians (AHMAC 2017).

Key findings

Overall: In New South Wales in 2012–13, based on measured and self-reported survey data, 26% of Indigenous adults had high blood pressure (Table 1.07.4). The age-standardised proportion with high blood pressure was similar for Indigenous and non-Indigenous Australians (31% compared with 30%). The rate for Indigenous Australians was higher in Remote areas (47%) than in Non-remote areas (31%) (Table 1.07.7, Figure 1.07.1). Nationally, based on a combination of self-reported and measured high blood pressure, 27% of Indigenous adults had high blood pressure (Table 1.07.4). The age-standardised proportion of Indigenous Australians with high blood pressure (33%) was higher than for non-Indigenous Australians (29%). Rates for Indigenous Australians were higher in Remote areas (40%) than in Non-remote areas (31%) (Table 1.07.7, Figure 1.07.1).

Hospitalisation overall: In New South Wales between July 2013 and June 2015, the age-standardised rate of hospitalisation for high blood pressure was higher for Indigenous Australians (0.7 per 1,000) than for non-Indigenous Australians (0.3 per 1,000). Nationally, rates were also higher for Indigenous Australians (0.9 per 1,000) than for non-Indigenous Australians (0.4 per 1,000) (Table 1.07.10, Figure 1.07.2).

Hospitalisation by sex: In New South Wales between July 2013 and June 2015, the age-standardised rate of hospitalisation for high blood pressure for Indigenous females (0.9 per 1,000) was higher than for Indigenous males (0.6 per 1,000). Nationally, the age-standardised rate of hospitalisation for high blood pressure for Indigenous females (1.1 per 1,000) was higher than for Indigenous males (0.7 per 1,000) (Table 1.07.10, Figure 1.07.2).

Hospitalisation by age: In New South Wales between July 2013 and June 2015, the largest difference between Indigenous and non-Indigenous Australians hospitalised for high blood pressure was for those aged 35–44. The rate for Indigenous Australians (0.5 per 1,000) for this age group was 3.9 times the rate for non-Indigenous Australians (0.1 per 1,000). Nationally, the largest difference between Indigenous and non-Indigenous Australians hospitalised for high blood pressure was for those aged 45–54. The rate for Indigenous Australians for this age group (1.4 per 1,000) was 4.5 times the rate for non-Indigenous Australians (0.3 per 1,000) (Table 1.07.9 NSW, Figure 1.07.3).

Figure 1.07.3: Age-specific hospitalisation rate for hypertensive disease, by age group (years) and Indigenous status, New South Wales and Australia, July 2013 to June 2015

1.08 Cancer

Why it is important

This measure reports on the incidence, mortality and hospitalisations for selected cancers and for all cancers combined. Indigenous Australians have a higher rates of death due to cancer, and higher incidence of certain screen-detectable and many preventable cancers. They are also diagnosed at more advanced stages, and often with more complex comorbidities (Cunningham et al. 2008).

Key findings

Overall: In New South Wales in 2008–2012, the age-standardised incidence rate of cancer (based on registrations of newly diagnosed cancers) was higher for Indigenous Australians (525 per 100,000) than for non-Indigenous Australians (438 per 100,000).

In NSW, Vic, Qld, WA and the NT combined, the age-standardised incidence rate of cancer was higher for Indigenous Australians (484 per 100,000) than for non-Indigenous Australians (439 per 100,000) (Table 1.08.3, Figure 1.08.1).

Type of cancer: In New South Wales in 2008–2012, the age-standardised incidence rate of breast cancer in Indigenous females was lower than the rate for non-Indigenous females. The incidence rates of lung, bowel, digestive system (excluding bowel), and cervical cancers were higher for Indigenous Australians than for non-Indigenous Australians.

In NSW, Vic, Qld, WA and the NT combined, the age-standardised rates of lung, digestive system (excluding bowel), and cervical cancers were higher for Indigenous Australians than for non-Indigenous Australians. Incidence rates of bowel and breast cancer in females were lower for Indigenous than non-Indigenous Australians (Table 1.08.3, Figure 1.08.1).

Hospitalisation: In New South Wales between July 2013 and June 2015, the age-standardised hospitalisation rate for cancer was lower for Indigenous Australians (12 per 1,000) than for non-Indigenous Australians (13 per 1,000).

Nationally, the age-standardised rate was lower for Indigenous Australians (12 per 1,000) than non-Indigenous Australians (16 per 1,000) (Table 1.08.12, Figure 1.08.2).

Mortality: In New South Wales in 2011–2015, the age-standardised death rate for all cancers combined was 210 per 100,000 for Indigenous Australians, compared with 172 per 100,000 for non-Indigenous Australians.

In NSW, Qld, WA, SA and the NT combined, the age-standardised death rate for all cancers combined was 232 per 100,000 for Indigenous Australians, and 172 per 100,000 for non-Indigenous Australians (Table 1.23.2).

Trend over time: In New South Wales between 2004–05 and 2014–15, the age-standardised hospitalisation rate for Indigenous Australians for cancer rose from 6 to 12 per 1,000. The rate for non-Indigenous Australians fell from 14 to 13 per 1,000.

In NSW, Vic, Qld, WA, SA and the NT combined, the age-standardised hospitalisation rate for cancer for Indigenous Australians rose from 8 to 13 per 1,000. For non-Indigenous Australians, the rate rose from 16 to 17 per 1,000 in 2004–05 to 17 per 1,000 in 2009–10, and then fell to 16 per 1,000 in 2014–15 (Table 1.08.15 NSW, Figure 1.08.3). See Measure 1.23 for the cancer mortality trend over time.

Aboriginal and Torres Strait Islander Health Performance Framework 2017: New South Wales 35
1.09 Diabetes

Why it is important

This measure reports on the prevalence of diabetes for Indigenous Australians. Diabetes is a long-term chronic condition where blood glucose levels become too high. Over time, high blood glucose levels can damage various parts of the body, especially the heart and blood vessels, eyes, kidneys and nerves. It can result in permanent disability, mental health problems, reduced quality of life and premature death (AIHW 2015d; Burrow & Ride 2016). High blood glucose levels cause complications for both the mother and baby during pregnancy. Type 2 diabetes is a significant contributor to morbidity and mortality for Indigenous Australians (AIHW 2015d).

Key findings

Overall: In New South Wales in 2012–13, the age-standardised rate for Indigenous Australians aged 18 and over who had diabetes was 16%, 3 times as high as the rate for non-Indigenous Australians (5%). The prevalence of diabetes was derived using a combination of biomedical results and self-reported information on diabetes diagnosis and medication use.

Nationally, the age-standardised rate for Indigenous Australians aged 18 and over who had diabetes was 18%, 3.5 times the proportion for non-Indigenous Australians (5%) (Table 1.09.2, Figure 1.09.1).

Hospitalisation overall: In New South Wales between July 2013 and June 2015, the age-standardised hospitalisation rate for Indigenous Australians for diabetes was 4 times the rate for non-Indigenous Australians (5.2 per 1,000 compared with 1.3 per 1,000).

Nationally, the age-standardised hospitalisation rate for Indigenous Australians for diabetes was 4 times the rate for non-Indigenous Australians (6.6 per 1,000 compared with 1.6 per 1,000) (Table 1.09.8).

Hospitalisation by age: In New South Wales between July 2013 and June 2015, the hospitalisation rates for Indigenous Australians for diabetes increased with age from 0.2 per 1,000 in those aged 0–4, to 17 per 1,000 in those aged 65 and over. Hospitalisation rates for non-Indigenous Australians also increased with age, from 0.2 per 1,000 in those aged 0–4, to 4.5 per 1,000 in those aged 65 and over.

Nationally, the hospitalisation rates for Indigenous Australians for diabetes increased with age, from 0.2 per 1,000 in those aged 0–4, to 18 per 1,000 in those aged 65 and over. For non-Indigenous Australians, rates increased from 0.3 per 1,000 in those aged 0–4, to 5 per 1,000 for those aged 65 and over (Table 1.09.7 NSW, Figure 1.09.2).

Mortality: In New South Wales in 2011–2015, the age-standardised death rate due to diabetes for Indigenous Australians was 50 per 100,000, compared with 15 per 100,000 for non-Indigenous Australians.

In NSW, Qld, WA, SA and the NT combined, the age-standardised death rate due to diabetes was 87 per 100,000 for Indigenous Australians and 16 per 100,000 for non-Indigenous Australians (Table 1.23.2, Figure 1.09.3).

1.10 Kidney disease

Why it is important

This measure reports on prevalence, deaths and hospitalisation for chronic kidney disease, and incidence of treated end-stage kidney disease. Kidney disease can be a disease in its own right, or can be caused by the kidneys being permanently damaged by various acute illnesses or by progressive damage from other chronic conditions (AIHW 2011). If the kidneys cease functioning, this can cause death unless the person has regular dialysis or a new kidney is provided by transplant (AHMAC 2017).

Key findings

Overall: In New South Wales in 2011–13, the age-standardised rate of Indigenous Australians aged 18 and over with chronic kidney disease was 18%, based on biomedical results. This was 1.7 times the proportion for non-Indigenous Australians (11%).

Nationally, the age-standardised rate of Indigenous Australians aged 18 and over with chronic kidney disease was 22%, based on biomedical results. This was more than twice the proportion for non-Indigenous Australians (10%) (Table 1.10.1, Figure 1.10.1).

Hospitalisation: In New South Wales between July 2013 and June 2015, the age-standardised hospitalisation rate for chronic kidney disease (excluding dialysis) for Indigenous Australians was 2.4 times the rate for non-Indigenous Australians (4.0 compared with 1.7 per 1,000) (Table 1.10.7). The rate for Indigenous Australians increased with age, peaking in those aged 55–64 (11.3 per 1,000), which was 4.6 times the rate for non-Indigenous Australians aged 55–64 (2.4 per 1,000) (Table 1.10.6 NSW, Figure 1.10.2).

Nationally, the age-standardised hospitalisation rate for chronic kidney disease (excluding dialysis) for Indigenous Australians was 3.6 times the rate for non-Indigenous Australians (5.6 compared with 1.6 per 1,000) (Table 1.10.7). The rate for Indigenous Australians increased with age, peaking in those aged 55–64 (13 per 1,000), which was 5.8 times the rate for non-Indigenous Australians (2.2 per 1,000) (Table 1.10.6 NSW, Figure 1.10.2).

End-stage kidney disease: In New South Wales and the Australian Capital Territory in 2012–2014, the age-standardised incidence rate of treated end-stage kidney disease for Indigenous Australians) was 3.5 times the rate for non-Indigenous Australians (34 compared with 9.6 per 100,000). The rate for Indigenous females was 5 times the rate for non-Indigenous females (37 compared with 7 per 100,000). The rate for Indigenous males was 2.6 times the rate for non-Indigenous males (30 compared with 12 per 100,000).

Nationally, the age-standardised incidence rate of treated end-stage kidney disease for Indigenous Australians was 8.7 times the rate for non-Indigenous Australians (59 compared with 6.8 per 100,000). The rate for Indigenous females was 13 times the rate for non-Indigenous females (64 compared with 5 per 100,000). The rate for Indigenous males was 6.3 times the rate for non-Indigenous males (53 compared with 8.4 per 100,000) (Table 1.10.11).

Trend over time: The incidence rate of treated end-stage kidney disease for Indigenous Australians in New South Wales rose by 102% between 1996 and 2014, from 6.5 to 14.0 per 100,000.

Nationally, the incidence rate of treated end-stage kidney disease for Indigenous Australians rose by 39% between 1996 and 2014, from 22 to 36 per 100,000 (Table 1.10.15, Figure 1.10.3).

Figure 1.10.3: Incidence rate of end-stage kidney disease for Indigenous Australians, New South Wales and Australia, 1996–2014

1.11 Oral health

Why it is important

This measure reports on teeth and gum problems, and hospitalisations for dental problems. The 2 most common oral diseases are tooth decay and gum disease. If left untreated, these can cause discomfort and tooth loss, affecting a person’s ability to eat, speak and socialise (Williams et al. 2011). Oral diseases can exacerbate other chronic diseases (Jamieson et al. 2010) and are associated with cardiovascular diseases, diabetes, stroke and pre-term low birthweight (Roberts-Thomson et al. 2008; Williams et al. 2011).

Key findings

Overall: In New South Wales in 2014–15, 31% of Indigenous children aged 0–14 who were surveyed reported teeth or gum problems, a fall from 33% in 2008.

Nationally, 28% of Indigenous children aged 0–14 who were surveyed, reported teeth or gum problems, a fall from 32% in 2008 (Table 1.11.1, Figure 1.11.1).

Tooth loss: In New South Wales in 2012–13, 5.2% of Indigenous Australians aged 15 and over reported complete tooth loss (note that wisdom teeth are excluded from this category).

Nationally, in 2012–13, 4.7% of Indigenous Australians aged 15 and over reported complete tooth loss (note that wisdom teeth are excluded from this category) (Table 1.11.10, Figure 1.11.2).

Remoteness: In New South Wales in 2012–13, a higher proportion of Indigenous Australians in Remote areas reported complete tooth loss (7.8%) than in Non-remote areas (5.0%).

Nationally in 2012–13, a higher proportion of Indigenous Australians in Non-remote areas reported complete tooth loss (5.1%) than in Remote areas (3.3%) (Table 1.11.10, Figure 1.11.2).

Hospitalisation overall: In New South Wales between July 2013 and June 2015, the age-standardised hospitalisation rate for dental problems for Indigenous Australians was 1.2 times the rate for non-Indigenous Australians (1.6 compared with 1.3 per 1,000).

Nationally, the age-standardised hospitalisation rate for dental problems for Indigenous Australians was 1.2 times the rate for non-Indigenous Australians (1.8 compared with 1.5 per 1,000) (Table 1.11.21 NSW).

Hospitalisation by age: In New South Wales between July 2013 and June 2015, the hospitalisation rate for dental problems for Indigenous Australians was highest for those aged 0–4 (5.9 per 1,000), 1.8 times the rate for non-Indigenous Australians of the same age (3.3 per 1,000).

Nationally, the hospitalisation rate for dental problems for Indigenous Australians was highest for those aged 0–4 (6.9 per 1,000), almost double the rate for non-Indigenous children of the same age (3.6 per 1,000) (Table 1.11.21 NSW, Figure 1.11.3).

1.12 HIV/AIDS, hepatitis and sexually transmissible infections

Why it is important
This measure reports on the rates hepatitis B and C and some bacterial sexually transmissible infections. The bacterial sexually transmissible infections included are notified cases of chlamydia, gonorrhoea and non-congenital syphilis. These infections can have potentially serious consequences if left untreated. Hepatitis causes serious illness and can also progress to cirrhosis of the liver, cancer and premature death (ASHA 2016). Sexually transmissible infections can have serious long-term consequences (Bowden et al. 2002). Several of these infections can cause miscarriage (Campbell et al. 2011).

Key findings
Data for New South Wales are presented for those conditions where the data set had an adequate level of Indigenous identification.

Non-congenital syphilis: In New South Wales from July 2013 to June 2015, the age-standardised notification rate for non-congenital syphilis for Indigenous Australians was more than twice the rate for other Australians (37 compared with 16 per 100,000). The notification rate for non-congenital syphilis for Indigenous females was 6.5 times the rate for other females (23 compared with 4 per 100,000). The rate for Indigenous males was 1.8 times the rate for other males (51 compared with 29 per 100,000).

Nationally, the age-standardised notification rate for non-congenital syphilis for Indigenous Australians was 4.6 times the rate for other Australians (72 compared with 15 per 100,000). The notification rate for non-congenital syphilis for Indigenous females was 16 times the rate for other females (65 compared with 4 per 100,000). The rate for Indigenous males was 2.9 times the rate for other males (78 compared with 27 per 100,000) (Table 1.12.1, Figure 1.12.1).

HIV: In New South Wales in 2013–2015, the age-standardised notification rate for HIV for Indigenous Australians was lower than for other Australians (3.9 compared with 4.8 per 100,000).

Nationally, there were 3,137 notifications of HIV, an age-standardised rate of 5.5 per 100,000 for Indigenous Australians, compared with 4.5 per 100,000 for other Australians (Table 1.12.8, Figure 1.12.2).

Hepatitis B and hepatitis C: Data for Hepatitis B and C are not available for New South Wales, as the data sets are not considered to have an adequate level of Indigenous identification.

Nationally in 2013–2015, the age-standardised notification rate for hepatitis B for Indigenous Australians was 1.7 times the rate for other Australians (43 compared with 26 per 100,000). The age-standardised notification rate for hepatitis C for Indigenous Australians was 3.9 times the rate for other Australians (147 compared with 38 per 100,000) (Table 1.12.1, Figure 1.12.3).
1.13 Community functioning

Why it is important

This measure reports on factors used to describe community functioning for Indigenous Australians. This is the ability and freedom of community members and communities to determine the context of their lives and translate capability into action (AHMAC 2017).

Key findings

Connectedness to Country, land and history; culture and identity: In New South Wales in 2014–15, 70% of Indigenous Australians aged 15 and over reported that they recognised their homelands, 55% identified with a clan or language group, and 62% had attended an Indigenous cultural event in the previous 12 months.

Nationally, 74% of Indigenous Australians reported that they recognised their homelands, 62% identified with a clan or language group, and 63% had attended a cultural event in the previous 12 months (Table 1.13.12, Figure 1.13.1).

Resilience: In New South Wales in 2014–15, 85% of Indigenous Australians aged 15 and over reported that they did not avoid situations due to past discrimination, 84% agreed that their doctor could be trusted, 69% agreed that the local school could be trusted, 97% had participated in sport, social activities, or community activities in the previous 12 months, and 38% of employed people said work allowed them to fulfil cultural responsibilities.

Nationally, 86% of Indigenous Australians reported that they did not avoid situations due to past discrimination, 81% agreed that their doctor could be trusted, 70% agreed that the local school could be trusted, 97% had participated in sport, social activities, or community activities in the previous 12 months, and 41% of employed people said work allowed them to fulfil cultural responsibilities (Table 1.13.12, Figure 1.13.2).

Having a role, structure and routine: In New South Wales in 2014–15, 29% of Indigenous Australians aged 15 and over reported having lived in 1 dwelling in the previous 12 months.

Nationally, 32% of Indigenous Australians reported having lived in 1 dwelling in the previous 12 months (Table 1.13.12).

Feeling safe: In New South Wales in 2014–15, 79% of Indigenous Australians aged 15 and over reported that they had not experienced physical or threatened violence in the previous 12 months, 87% felt safe at home alone after dark, and 67% felt safe walking alone in the local area after dark.

Nationally, 78% of Indigenous Australians reported that they had not experienced physical or threatened violence in the previous 12 months, 87% felt safe at home alone after dark, and 68% felt safe walking alone in the local area after dark (Table 1.13.12, Figure 1.13.3).

Vitality: In New South Wales in 2014–15, of Indigenous Australians aged 15 and over, 39% self-assessed their health status as excellent or very good, 69% had experienced low/moderate levels of psychological distress in the previous 4 weeks, and 81% could easily get to places as needed.

Nationally, 40% of Indigenous Australians self-assessed their health status as excellent or very good, 67% had experienced low/moderate levels of psychological distress in the previous 4 weeks, and 75% could easily get to places as needed (Table 1.13.12).

1.14 Disability

Why it is important

This measure reports on the prevalence of disability for Indigenous Australians, including children with special needs and users of disability support services. Disability might be an impairment of body structure or function, a limitation in activities or a restriction in a person’s participation in specific activities. Indigenous Australians are at greater risk of disability due to increased exposure to factors such as low birthweight, chronic disease, infectious diseases, injury and substance use (AHMAC 2017).

Key findings

Overall: In New South Wales in 2014–15, 48% of Indigenous Australians aged 15 and over, reported having a disability or restrictive long-term health condition (Table 1.14.2). The age-standardised rate for Indigenous Australians reporting having a disability or restrictive long-term health condition was 53%, compared with 29% of non-Indigenous Australians (Table 1.14.1, Figure 1.14.1).

Nationally, 45% of Indigenous Australians aged 15 and over reported having a disability or restrictive long-term health condition (Table 1.14.2). The age-standardised rate for Indigenous Australians reporting having a disability or restrictive long-term health condition was 1.8 times higher than the rate for non-indigenous Australians (50% compared with 30%) (Table 1.14.1, Figure 1.14.1).

Assistance with core-activities: In New South Wales in 2011, Census data showed that 6.6% of Indigenous Australians needed assistance with a core-activity (self-care, mobility or communication) some or all of the time. The age-standardised rate for Indigenous Australians needing assistance with core-activities was 2.1 times the rate for non-Indigenous Australians (9.6% compared with 4.6%).

Nationally, 5.7% of Indigenous Australians needed assistance with a core-activity. The age-standardised rate for Indigenous Australians was 2 times the rate for non-Indigenous Australians (9.2% compared with 4.5%) (Table 1.14.12, Figure 1.14.2).

Users of disability support services: In New South Wales in 2014–15, the age-standardised rate for Indigenous Australians aged under 65 who had used disability support services was 33 per 1,000. This was 2.4 times the rate for non-Indigenous Australians (14 per 1,000). The rate for Indigenous males was higher than for Indigenous females (41 and 25 per 1,000). The rate for non-Indigenous males was higher than for non-Indigenous females (17 per 1,000, compared with 11 per 1,000).

Nationally, the age-standardised rate for Indigenous Australians aged under 65 who had used disability support services was 28 per 1,000. This was 1.9 times the rate for non-Indigenous Australians (15 per 1,000). The rate was higher for Indigenous males than Indigenous females (33 and 23 per 1,000), and for non-Indigenous males compared with non-Indigenous females (17 and 12 per 1,000) (Table 1.14.16, Figure 1.14.3).

Trend over time: Comparable trend data are not available for individual jurisdictions.

1.15 Ear health

Why it is important

This measure reports on hearing health in children and adults, including prevalence rates for ear and hearing problems, hospitalisation rates for disease of the ear and mastoid process, and rates of ear and hearing problems managed at consultations with GPs. Hearing loss, especially in childhood, can result in poorer educational achievements, and have lifelong consequences (Williams & Jacobs 2009).

Key findings

Overall: In New South Wales in 2012–13, 13% of Indigenous Australians reported having ear or hearing problems (Table 1.15.4). The age-standardised rate for Indigenous Australians reporting an ear or hearing problem was 1.4 times the rate for non-Indigenous Australians (16.4% compared with 11.6%).

Nationally, the age-standardised rate for Indigenous Australians reporting an ear or hearing problem was 1.3 times the rate for non-Indigenous Australians (16.0% compared with 12.2%) (Table 1.15.5).

Remoteness: In New South Wales in 2012–13, the rate for Indigenous Australians (all ages) reporting ear and hearing problems was higher in Remote than Non-remote areas (16% and 12% respectively).

Nationally, the rate for Indigenous Australians (all ages) reporting ear and hearing problems was similar in Remote and Non-remote areas (12% and 13%, respectively) (Table 1.15.4, Figure 1.15.1).

Children aged 0–14: In New South Wales in 2014–15, based on reported information, 8.0% of Indigenous children had an ear or hearing problem (Table 1.15.9). Between July 2013 and June 2015, the age-standardised hospitalisation rate for diseases of the ear and mastoid process for Indigenous children was similar to the rate for non-Indigenous children (6.0 compared with 6.3 per 1,000). The rate for Indigenous males was higher than the rate for Indigenous females (6.9 compared with 5.1 per 1,000) (Table 1.15.10, Figure 1.15.2).

Nationally, based on reported information, 8.4% of Indigenous children had an ear or hearing problem (Table 1.15.9). The age-standardised hospitalisation rate for diseases of the ear and mastoid process for Indigenous children was higher than the rate for non-Indigenous children (7.5 compared with 6.7 per 1,000). The age-standardised hospitalisation rate for Indigenous males was higher than the rate for Indigenous females (8.0 compared with 7.0 per 1,000) (Table 1.15.10, Figure 1.15.2).

Trend over time: In New South Wales, the age-standardised hospitalisation rate for diseases of the ear and mastoid process for Indigenous Australians of all ages rose from 1.8 per 1,000 in 2004–05 to 2.5 per 1,000 in 2014–15. The rate for non-Indigenous Australians remained steady (2.3 compared with 2.4 per 1,000).

For NSW, Vic, Qld, WA, SA and the NT combined, the age-standardised hospitalisation rate for diseases of the ear and mastoid process for Indigenous Australians (all ages) rose from 2.4 per 1,000 in 2004–05 to 3.2 per 1,000 in 2014–15. The rate for non-Indigenous Australians did not change (2.6 per 1,000) (Table 1.15.15 NSW, Figure 1.15.3).

Figure 1.15.3: Age-standardised hospitalisation rate for diseases of the ear and mastoid process, by Indigenous status, New South Wales and NSW, Vic, Qld, WA, SA and NT combined, 2004–05 to 2014–15

1.16 Eye health

Why it is important

This measure reports on prevalence of eye health problems, including low vision, blindness, refractive error, cataract, diabetic retinopathy, and trachoma for Indigenous Australians. The partial or full loss of vision affects all dimensions of life. Vision loss and eye disease can lead to linguistic, social and learning difficulties, as well as behavioural problems during schooling years, which can then lead to poor education outcomes and employment prospects. Indigenous Australians have higher rates of cataract, diabetic retinopathy and trachoma than non-Indigenous Australians (AHMAC 2017).

Key findings

Overall: In New South Wales in 2014–15, 20% of Indigenous Australians aged 15 and over reported having eye or sight problems. The rate in Remote areas was higher than in Non-remote areas (25% compared with 20%).

Nationally, 19% of Indigenous Australians aged 15 and over reported having eye or sight problems. The rate in Remote areas was lower than the rate in Non-remote areas (16% compared with 20%) (Table 1.16.5, Figure 1.16.1).

Reported eye and sight problems: In 2012–13 in New South Wales, the age-standardised rate for Indigenous Australians who reported having eye or sight problems was 0.9 times the rate for non-Indigenous Australians (50% compared with 53%).

Nationally in 2012–13, the age-standardised rate for Indigenous Australians who reported having eye or sight problems was also 0.9 times the rate for non-Indigenous Australians (48% compared with 53%) (Table 1.16.6).

Hospitalisation: In New South Wales between July 2013 and June 2015, the age-standardised hospitalisation rate for Indigenous Australians for diseases of the eye and adnexa was 0.7 times the rate for non-Indigenous Australians (9.3 per 1,000 compared with 12.6 per 1,000). The rate increased with age, from 1.2 per 1,000 for those aged 0–4 to 49 per 1,000 for those aged 65 and over.

Nationally, the age-standardised hospitalisation rate for Indigenous Australians for diseases of the eye and adnexa was 0.8 times the rate for non-Indigenous Australians (10 per 1,000 compared with 13 per 1,000). The rate increased with age for Indigenous Australians, from 1.5 per 1,000 for those aged 0–4 to 51 per 1,000 for those aged 65 and over (Table 1.16.12 NSW).

Trend over time: In New South Wales, the age-standardised hospitalisation rate for Indigenous Australians for diseases of the eye and adnexa rose from 3.5 per 1,000 in 2004–05 to 10 per 1,000 in 2014–15. The rate for non-Indigenous Australians rose from 10 to 13 per 1,000.

In NSW, Vic, Qld, WA, SA and the NT combined, the age-standardised hospitalisation rate for Indigenous Australians for diseases of the eye and adnexa rose from 5.4 in 2004–05 to 11 per 1,000 in 2014–15. The rate for non-Indigenous Australians rose from 9.5 to 14 per 1,000 (Table 1.16.18 NSW, Figure 1.16.3).

Source: Table 1.16.18 NSW.

1.17 Perceived health status

Why it is important
This measure reports on self-assessed health status of Indigenous Australians. Self-assessed health status provides a measure of the overall level of a population's health based on individuals' personal perceptions of their own health. Self-assessed health status is dependent on an individual's awareness and expectations about their health. It is influenced by various factors, including access to health services and information, the extent to which health conditions have been diagnosed and level of education (Delpierre et al. 2009).

Key findings

Overall: In New South Wales in 2014–15, 39% of Indigenous Australians aged 15 and over self-assessed their health as excellent/very good, 34% as good, and 26% as fair/poor.

Nationally in 2014–15, 40% of Indigenous Australians aged 15 and over self-assessed their health as excellent/very good, 35% as good, and 26% as fair/poor (Table 1.17.8, Figure 1.17.1).

Excellent/very good health: In New South Wales in 2014–15, the age-standardised rate for Indigenous Australians that self-assessed their health as excellent/very good was 0.6 times the rate for non-Indigenous Australians (34% compared with 57%).

Nationally, the age-standardised rate for Indigenous Australians who self-assessed their health as excellent/very good was 0.6 times the rate for non-Indigenous Australians (35% compared with 57%) (Table 1.17.9, Figure 1.17.2).

Good health: In New South Wales in 2014–15, the age-standardised rate for Indigenous Australians who self-assessed their health as good was 1.1 times the rate for non-Indigenous Australians (34% compared with 30%).

Nationally, the age-standardised rate for Indigenous Australians who self-assessed their health as good was 1.2 times the rate for non-Indigenous Australians (35% compared with 29%) (Table 1.17.9, Figure 1.17.2).

Fair/poor health: In New South Wales in 2014–15, the age-standardised rate for Indigenous Australians who self-assessed their health as fair/poor (32%) was 2.3 times the rate for non-Indigenous Australians (14%).

Nationally, the age-standardised rate for Indigenous Australians who self-assessed their health as fair/poor (31%) was 2.2 times the rate for non-Indigenous Australians (14%) (Table 1.17.9, Figure 1.17.2).

Trend over time: In New South Wales the proportion of Indigenous Australians aged 15 and over who self-assessed their health as excellent/very good fell slightly from 43% in 2002 to 39% in 2014–15.

Nationally the proportion of Indigenous Australians who self-assessed their health as excellent/very good fell slightly between 2002 and 2014–15, from 44% to 40% (Table 1.17.8, Figure 1.17.3).

Figure 1.17.3: Self-assessed health status of Indigenous Australians (aged 15 and over), New South Wales and Australia, 2002 to 2014–15

1.18 Social and emotional wellbeing

Why it is important

This measure reports on the social and emotional wellbeing of Indigenous Australians. This is a holistic concept for Indigenous Australians, health is not just the physical wellbeing of the individual but the social, emotional and cultural wellbeing of the whole community (Dudgeon et al. 2014; Gee et al. 2014; SHRG 2004).

Key findings

**Overall:** In New South Wales in 2012–13, the age-standardised rate for Indigenous Australians aged 18 and over who reported high or very high levels of psychological distress was 31% compared with 10% for non-Indigenous Australians.

Nationally, the age-standardised rate for Indigenous Australians aged 18 and over who reported high or very high levels of psychological distress was 30% compared with 11% for non-Indigenous Australians (Table 1.18.3, Figure 1.18.1).

**Hospitalisation:** In New South Wales between July 2013 and June 2015, the age-standardised hospitalisation rate for Indigenous Australians for mental health-related conditions was 30 per 1,000 compared with 18 per 1,000 for non-Indigenous Australians. The highest hospitalisation rate for Indigenous Australians was for those aged 35–44, at 56 per 1,000 compared with 26 per 1,000 for non-Indigenous Australians.

Nationally, the age-standardised hospitalisation rate for mental health-related conditions was 29 per 1,000 for Indigenous Australians, compared with 16 per 1,000 for non-Indigenous Australians. The highest rate was also for those aged 35–44, at 52 per 1,000 for Indigenous Australians compared with 22 per 1,000 for non-Indigenous Australians (Table 1.18.14 NSW, Figure 1.18.2).

**Deaths:** In New South Wales in 2011–2015, the age-standardised death rate for Indigenous Australians in from intentional self-harm, was 14 deaths per 100,000. This was 1.4 times the rate for non-Indigenous Australians of 10 deaths per 100,000.

For NSW, Qld, WA, SA and the NT combined, the age-standardised death rate for Indigenous Australians from intentional self-harm was 23 deaths per 100,000. This was 2.1 times the rate for non-Indigenous Australians of 11 deaths per 100,000 (Table 1.18.30).

**Trend over time:** In New South Wales between 1998 and 2015, the death rate for intentional self-harm for Indigenous and non-Indigenous Australians was too variable to assess a trend. Age-standardised death rates were not calculated due to the small numbers involved.

For NSW, Qld, WA, SA and the NT combined, the age-standardised death rate from intentional self-harm for Indigenous Australians from 1998 to 2015 rose by 32%, varying from 13 per 100,000 in 1999 to 26 per 100,000 in 2015. The rate for non-Indigenous Australians varied between 9.7 per 100,000 in 2004 and 14.5 per 100,000 in 1998, but over the whole period fell by 13% from 1998 to 2015 (Table 1.18.26, Figure 1.18.3).

1.19 Life expectancy at birth

Why it is important

This measure reports on life expectancy at birth. Life expectancy refers to the average number of years a person of a given age and sex can expect to live, if current age and sex-specific death rates continue to apply throughout his or her lifetime. It is widely used internationally as a measure of the general health of populations. There is currently a large gap in life expectancy between Indigenous and non-Indigenous Australians. Social and economic factors such as poverty, racism, stressors, educational exposure and employment status affect the individual’s likelihood to engage in health risk behaviours as well as their access to the health system. These factors combined lead to increased risk of circulatory disease (Dong et al. 2004) and cancer (Kelly-Irving et al. 2013) the leading causes of death.

Key findings

Overall: According to the ABS, in New South Wales in 2010–2012, life expectancy at birth was estimated to be 70.5 years for Indigenous males, and 74.6 years for Indigenous females. These estimates were lower than for non-Indigenous males and females (79.8 years and 83.1 years, respectively). This represents a gap of 9.3 years for males and 8.5 years for females.

Nationally in 2010–2012, life expectancy at birth was estimated to be 69.1 years for Indigenous males and 73.7 years for Indigenous females. For non-Indigenous Australians the estimate was 79.7 years for males, and 83.1 years for females, a gap of 10.6 years for males and 9.5 years for females (Table 1.19.1, Figure 1.19.1).

Remoteness: Life expectancy estimates that are broken down by remoteness area are not available for individual jurisdictions.

Nationally in 2010–2012, life expectancy for Indigenous males living in Outer regional, Remote and Very remote areas combined, was estimated to be 0.7 years lower than for Indigenous males living in Major cities and Inner regional areas combined (67.3 compared with 68.0 years). For Indigenous females living in Outer regional, Remote and Very remote areas combined, life expectancy was 0.8 years lower than for Indigenous females living in Major cities and Inner regional areas combined (72.3 years compared with 73.1 years) (AHMAC 2017, Figure 1.19.2).

Over time: In New South Wales between 2005–2007 and 2010–2012, the life expectancy of Indigenous males rose from 68.3 to 70.5 years, for Indigenous females it rose from 74.0 to 74.6 years. The life expectancy of non-Indigenous males and females also rose, from 78.8 to 79.8 years for males, and from 82.6 to 83.1 years for females.

The gap between Indigenous and non-Indigenous Australians in New South Wales narrowed for both males (from 10.5 to 9.3 years) and females (from 8.6 to 8.5 years).

Nationally, life expectancy between 2005–2007 and 2010–2012 rose for both Indigenous males and females, by 1.6 and 0.6 years, respectively. The gap between Indigenous and non-Indigenous Australians narrowed from 11.4 to 10.6 years for Indigenous males, and from 9.6 to 9.5 years for Indigenous females (Table 1.19.1, Figure 1.19.3). National life expectancy estimates presented in this measure were calculated using a different method to the estimates in Table S1. The estimates in this measure are comparable across 2 time points. The estimates in Table S1 enable comparison between the national and jurisdiction estimates (ABS 2013a).

Figure 1.19.2: Life expectancy at birth, Indigenous Australians, by remoteness area and sex, Australia, 2010–2012

Figure 1.19.3: Life expectancy at birth, by sex and Indigenous status, New South Wales and Australia, 2005–2007 and 2010–2012

1.20 Infant and child mortality

Why it is important

This measure reports on the death rates of Indigenous infants and children aged 0–4 years, by cause of death. Infant mortality is a long established measure of child health, as well as the overall health of the population, and its physical and social environment (AHMAC 2017).

Key findings

Overall: In New South Wales in 2011–2015, the death rate for Indigenous children aged 0–4 was 1.4 times the rate for non-Indigenous children (111 compared with 81 per 100,000). For NSW, Qld, WA, SA, and the NT combined, the death rate for Indigenous children aged 0–4 was 2.1 times the rate for non-Indigenous children (165 compared with 80 per 100,000) (Table 1.20.1, Figure 1.20.1).

Infant mortality: In New South Wales in 2011–2015, the death rate for Indigenous infants was 1.2 times the rate for non-Indigenous infants (4.0 compared with 3.3 per 1,000 live births), but the ratio was not statistically significant. For NSW, Qld, WA, SA, and the NT combined, the rate for Indigenous infants was 1.9 times the rate for non-Indigenous infants (6.1 compared with 3.3 per 1,000 live births) (Table 1.20.4, Figure 1.20.2).

SIDS mortality: In New South Wales in 2011–2015, the death rate from sudden infant death syndrome (SIDS) for Indigenous infants was 2.1 times the rate for non-Indigenous infants, 0.3 per 1,000 live births compared with 0.1 per 1,000 live births. For NSW, Qld, WA, SA, and NT combined, the SIDS death rate for Indigenous infants was 3.1 times the rate for non-Indigenous infants, 0.5 per 1,000 live births compared with 0.2 per 1,000 live births (Table 1.20.6).

Trend over time: In New South Wales between 1998 and 2015, the death rate for Indigenous children aged 0–4 fell by 29% (from 129 to 104 per 100,000), but this was not statistically significant. For non-Indigenous children, there was a 32% significant fall (from 102 to 78 per 100,000) (Table 1.20.16). For Qld, WA, SA, and the NT combined, the death rate for Indigenous children aged 0–4 fell by a statistically significant 35% (from 202 to 156 per 100,000). For non-Indigenous children, there was a 37% significant fall (from 104 to 70 per 100,000) (Table 1.20.17).

In New South Wales, the infant death rate fell from 11.7 per 1,000 live births in 1998–2000 to 5.2 per 1,000 live births in 2013–2015 (deaths are presented in 3-year groupings because of the small numbers in each year). The gap between Indigenous and non-Indigenous infant mortality narrowed over this time, from 7.3 to 1.6 per 1,000 (Table 1.20.9, Figure 1.20.3). For NSW, Qld, WA, SA, and the NT combined, the death rate for Indigenous infants fell from 13.5 per 1,000 in 1998 to 6.3 per 1,000 in 2015. The gap significantly narrowed, from 9.1 in 1998 to 3.0 in 2015 (Table 1.20.8, Figure 1.20.3).
Figure 1.20.1: Death rate of children (aged 0–4), by Indigenous status, New South Wales and NSW, Qld, WA, SA and NT combined, 2011–2015

Figure 1.20.2: Death rate of infants (aged 0–1), by Indigenous status, New South Wales and NSW, Qld, WA, SA and NT combined, 2011–2015

Figure 1.20.3: Death rate of infants (aged <1 year), by Indigenous status, New South Wales, 1998–2000 to 2013–2015, and NSW, Qld, WA, SA and NT combined, 1998–2015

Perinatal mortality

Why it is important

This measure reports on the number of Indigenous babies who die in the perinatal period. The perinatal death rate includes fetal deaths (stillbirths) and deaths of live born babies within the first 28 days after birth. Perinatal mortality reflects the health status and health care of the general population, access to and quality of preconception, reproductive, antenatal and obstetric services for women, and health care in the neonatal period. Broader social factors such as maternal education, nutrition, smoking, alcohol use in pregnancy and socioeconomic disadvantage are also significant (AHMAC 2017).

Key findings

**Overall:** In New South Wales in 2011–2015, the perinatal death rate for Indigenous babies was lower than the rate for non-Indigenous babies (5.9 per 1,000 births compared with 7.4 per 1,000 births).

In 2011–2015 in NSW, Qld, WA, SA and the NT combined, the perinatal death rate for Indigenous babies was 1.2 times the rate for non-Indigenous babies (9.2 per 1,000 births compared with 7.7 per 1,000 births) (Table 1.21.4, Figure 1.21.1).

**Fetal deaths:** In New South Wales in 2011–2015, fetal deaths (stillbirths) accounted for 57% of perinatal deaths for Indigenous babies and 67% for non-Indigenous babies. This was a rate of 3.4 deaths per 1,000 births for Indigenous babies, compared with 4.9 per 1,000 for non-Indigenous babies.

In 2011–2015 in NSW, Qld, WA, SA and the NT combined, fetal deaths (stillbirths) accounted for 59% of perinatal deaths for Indigenous babies and 70% for non-Indigenous babies (Table 1.21.4, Figure 1.21.1).

**Neonatal deaths:** In New South Wales in 2011–2015, neonatal deaths accounted for 43% of perinatal deaths for Indigenous babies. The rate of neonatal deaths was the same for Indigenous and non-Indigenous babies, 2.5 per 1,000 live births.

In 2011–2015 in NSW, Qld, WA, SA and the NT combined, the rate of neonatal deaths for Indigenous babies was 1.6 times the rate for non-Indigenous babies (3.8 per 1,000 compared with 2.3 per 1,000) (Table 1.21.4, Figure 1.21.1).

**Over time:** In New South Wales in 2011–2015, the rate of perinatal deaths for Indigenous babies in 2011–2015 was lower than the rate in 2006–2010 (5.9 compared with 6.8 per 1,000 births), however the difference was not statistically significant. For non-Indigenous babies, the rate of perinatal deaths in 2011–2015 was similar to the rate in 2006–2010 (7.4 compared with 7.6 per 1,000 births) (Table 1.21.4, Figure 1.21.2).

Over the longer term, in NSW, Qld, WA, SA and the NT combined, the fetal death rate for Indigenous babies fell by 53%—from 10.4 per 1,000 births in 1998 to 6.0 per 1,000 births in 2015. The neonatal death rate for Indigenous babies also fell over this time (by 60%), from 7.7 per 1,000 births in 1998 to 3.9 per 1,000 births in 2015 (Table 1.21.3, Figure 1.21.3).

Figure 1.21.3: Fetal and neonatal death rate, Indigenous Australians, NSW, Qld, WA, SA and NT combined, 1998–2015

1.22  All causes age-standardised death rates

Why it is important
This measure reports on the death rate from all causes. The death rate of a population provides a summary measure of the overall health status of that population. Death rates are a useful measure with which to compare the overall health status of different populations and to monitor changes in overall health status of populations over time. The rate for Indigenous Australians is 1.7 times that for non-Indigenous Australians, indicating that the overall health status is worse for Indigenous Australians. Mortality rates are also used as an annual progress measure for the COAG target to close the gap in life expectancy by 2031, as life expectancy estimates are only available every 5 years (AHMAC 2017).

Key findings

Overall: In New South Wales in 2011–2015, there were 3,730 deaths of Indigenous Australians. The age-standardised death rate for Indigenous Australians was 1.4 times the rate for non-Indigenous Australians (810 compared with 585 per 100,000).

For NSW, Qld, WA, SA and the NT combined, the age-standardised death rate for Indigenous Australians was 1.7 times the rate for non-Indigenous Australians (992 compared with 580 per 100,000) (Table 1.22.3, Figure 1.22.1).

The gap between Indigenous and non-Indigenous Australians: In New South Wales in 2011–2015, the gap in the age-standardised death rate between Indigenous and non-Indigenous Australians was 225 per 100,000.

In NSW, Qld, WA, SA and the NT combined, the gap in the age-standardised death rate between Indigenous and non-Indigenous Australians was 412 per 100,000 (Table 1.22.3).

Trend over time, age-standardised death rate: In New South Wales between 1998 and 2015, the age-standardised death rate for Indigenous Australians did not change significantly. But for non-Indigenous Australians, the rate fell by a significant 15% (from 687 to 584 per 100,000) (Table 1.22.6, Figure 1.22.2).

In NSW, Qld, WA, SA and the NT combined, the age-standardised death rate for Indigenous Australians fell by a significant 15% (from 1,180 to 1,000 per 100,000). For non-Indigenous Australians, it fell by a significant 17% (from 700 to 579 per 100,000) (Table 1.22.5, Figure 1.22.2).

Trend over time, the gap between Indigenous and non-Indigenous Australians: In New South Wales between 1998 and 2015, the gap in the age-standardised death rate between Indigenous and non-Indigenous Australians widened significantly (from 107 to 208 per 100,000) (Table 1.22.6).

In NSW, Qld, WA, SA and the NT combined, there was no significant change in the age-standardised gap between Indigenous and non-Indigenous Australians (from 479 to 421 per 100,000) (Table 1.22.5).

Trajectory for closing the gap in mortality: Death rates relate to the COAG target to close the gap in life expectancy within a generation. In New South Wales over the long-term, death rates for Indigenous Australians have not improved, and a considerable fall is required to reach the target in 2031 (Figure 1.22.3).
1.23 Leading causes of mortality

Why it is important

This measure reports on the main causes of death. Death rates are a useful measure of the overall health status of a population, or to measure improvements over time. The gap between the Indigenous and non-Indigenous populations for particular causes of death provides an indication of the prevention, prevalence and management of particular diseases, helping to determine the diseases that have most affect Indigenous Australians (AHMAC 2017).

Key findings

Overall: In 2011–2015 in New South Wales, the age-standardised rates for the most common causes of death for Indigenous and non-Indigenous Australians were: circulatory diseases (233 compared with 178 per 100,000—see below); cancers (210 compared with 172 per 100,000—see below); respiratory diseases (90 compared with 51 per 100,000); external causes (65 compared with 35 per 100,000); and endocrine, metabolic and nutritional disorders (57 compared with 22 per 100,000).

For NSW, Qld, WA, SA and the NT combined, the age-standardised rates for the most common causes of death for Indigenous and non-Indigenous Australians were: circulatory diseases (271 compared with 173 per 100,000); neoplasms (232 compared with 172 per 100,000); respiratory diseases (101 compared with 50 per 100,000); endocrine, metabolic and nutritional disorders (101 compared with 23 per 100,000); and external causes (81 compared with 38 per 100,000) (Table 1.23.2, Figure 1.23.1).

Chronic disease death: In 2011–2015 in New South Wales, the age-standardised death rate for chronic diseases for Indigenous Australians aged 0–74 was 2.1 times the rate for non-Indigenous Australians (340 compared with 162 per 100,000).

In NSW, Qld, WA, SA and the NT combined, the rate for Indigenous Australians was 2.8 times the rate for non-Indigenous Australians (447 compared with 159 per 100,000) (Table 1.23.5).

Trend over time, circulatory disease: From 1998 to 2015 in New South Wales, the age-standardised death rate for circulatory diseases for Indigenous Australians fell by 38% (from 337 per 100,000 in 1998 to 210 per 100,000 in 2015). The gap between Indigenous and non-Indigenous Australians narrowed by 21%, but this was not statistically significant.

In NSW, Qld, WA, SA and the NT combined, the age-standardised death rate for circulatory diseases for Indigenous Australians fell by 43% (from 462 in 1998 to 263 per 100,000 in 2015). The gap narrowed by 42% (from 169 to 98 per 100,000) (Table 1.23.28, Figure 1.23.2).

Trend over time, cancer: In New South Wales between 1998 and 2015, the age-standardised death rate for cancer for Indigenous Australians rose by 41% (from 138 per 100,000 in 1998 to 215 per 100,000 in 2015). The rate for non-Indigenous Australians fell by 10% (from 189 to 169 per 100,000).

In NSW, Qld, WA, SA and the NT combined, the age-standardised death rate for cancer for Indigenous Australians rose by 21% (from 185 to 241 per 100,000). The rate for non-Indigenous Australians fell by 13% (from 194 to 168 per 100000) (Table 1.23.29, Figure 1.23.3).

1.24 Avoidable and preventable deaths

Why it is important

This measure reports on potentially avoidable deaths of Indigenous Australians aged 0–74. Avoidable death refers to deaths from conditions that are considered avoidable, given timely and effective health care (including disease prevention and population health initiatives) (AIHW 2010b; Page et al. 2006). Avoidable deaths have been used in various studies to measure the quality, effectiveness and accessibility of the health system. Deaths from most conditions are influenced by various factors in addition to health system performance, including the underlying prevalence of conditions in the community, environmental and social factors and health behaviours (AHMAC 2017).

Key findings

**Overall:** In 2011–2015 in New South Wales, 1,612 Indigenous Australians aged 0–74 died from avoidable causes. The age-standardised avoidable death rate for Indigenous Australians was 2.3 times the rate for non-Indigenous Australians (244 compared with 104 per 100,000).

In NSW, Qld, WA, SA and the NT combined, the age-standardised avoidable death rate for Indigenous Australians was 3.3 times the rate for non-Indigenous Australians (345 compared with 105 per 100,000) (Table 1.24.4, Figure 1.24.1).

The gap between Indigenous and non-Indigenous Australians: In New South Wales in 2011–2015, the gap in the age-standardised death rate between Indigenous and non-Indigenous Australians due to avoidable causes was 139 per 100,000.

In NSW, Qld, WA, SA and the NT combined, the gap in the age-standardised death rate between Indigenous and non-Indigenous Australians for avoidable causes was 240 per 100,000 (Table 1.24.4).

**Trend over time:** For NSW, Qld, WA, SA and the NT combined, the age-standardised avoidable mortality rate for Indigenous Australians fell from 497 per 100,000 in 1998 to 345 per 100,000 in 2015. The age-standardised avoidable mortality rate for non-Indigenous Australians fell from 178 per 100,000 in 1998 to 104 per 100,000 in 2015 (Table 1.24.2, Figure 1.24.2).

This page intentionally left blank.
Tier 2—Determinants of health
2.01 Housing

Why it is important

This measure reports on the housing circumstances of Indigenous Australians, including overcrowding (based on the Canadian National Occupancy Standard for Housing Appropriateness), tenure type and homelessness. Housing circumstances affect health and wellbeing (Andersen et al. 2016). There are complex relationships between housing circumstances, health and socioeconomic factors such as education, income and employment (Thomson et al. 2013).

Key findings

Home owners: In 2014–15 in New South Wales, 34% of Indigenous Australians aged 18 and over reported owning their homes, compared with 67% of non-Indigenous Australians. Nationally, 29% of Indigenous Australians owned their homes, compared with 69% of non-Indigenous Australians (Table 2.01.17, Figure 2.01.1).

Renters: In 2014–15 in New South Wales, 64% of Indigenous Australians reported that they rented, compared with 30% of non-Indigenous Australians. A higher proportion of Indigenous Australians (18%) rented through state or territory housing authorities (organisations subsidised by public funds) than non-Indigenous Australians (3%). For other organisations (housing co-operatives, church groups and Indigenous housing organisations) the rates for Indigenous and non-Indigenous Australians were 3% and 0.6%, respectively. Nationally, 70% of Indigenous Australians rented, compared with 29% of non-Indigenous Australians. A higher proportion of Indigenous Australians rented through state or territory housing authorities (23% for Indigenous Australians and 3% for non-Indigenous Australians) or other organisations (12% and 0.5%, respectively) (Table 2.01.17, Figure 2.01.1).

Overcrowding: In 2014–15 in New South Wales, 14% of Indigenous Australians reported living in overcrowded households, compared with 7% of non-Indigenous Australians. Nationally, 21% of Indigenous Australians lived in overcrowded households, compared with 6% of non-Indigenous Australians (Table 2.01.2, Figure 2.01.2).

Remoteness: In 2014–15 in New South Wales, 14.4% of Indigenous Australians in Remote areas reported living in overcrowded households, compared with 14% in Non-remote areas. Nationally, 41% of Indigenous Australians in Remote areas lived in overcrowded households, compared with 15% in Non-remote areas (Table 2.01.2, Figure 2.01.2).

Specialist homelessness services: In 2014–15 in New South Wales, the rate of specialist homelessness services use by Indigenous Australians (all ages) was 10.1 times the rate for non-Indigenous Australians (480 compared with 48 per 10,000). Nationally, the rate was 8.7 times the rate for non-Indigenous Australians (693 compared with 80 per 10,000) (Table 2.01.30, Figure 2.01.3).

Trend over time: Between 2004–05 and 2014–15 in New South Wales, the proportion of Indigenous Australians that reported they live in overcrowded households varied between a high of 18% and a low of 12%.

Nationally between 2004–05 and 2014–15, the proportion of Indigenous Australians living in overcrowded households fell from 27% to 21% (Table 2.01.24).

Figure 2.01.2: Proportion of Australians living in overcrowded households, by remoteness area and Indigenous status, New South Wales and Australia, 2014–15

Figure 2.01.3: Rate of specialist homelessness service use, by Indigenous status, New South Wales and Australia, 2014–15

2.02 Access to functional housing with utilities

Why it is important

This measure reports on connection to water, sewerage and electricity, and the overall functionality of Indigenous housing facilities needed for healthy living. Housing is important for health and wellbeing. Functional housing encompasses basic services and facilities, infrastructure and habitability. These factors combined enable households to carry out healthy living practices including: waste removal; maintaining cleanliness through washing people, clothing and bedding; managing environmental risk factors such as electrical safety and temperature in the living environment; controlling air pollution for allergens; and preparing food safely (Bailie & Wayte 2006; DFCS 2003; Nganampa Health Council et al. 1987).

Key findings

Overall: In 2014–15 in New South Wales, 17.6% of Indigenous Australians reported living in dwellings of an unacceptable standard.

Nationally, 18.2% of Indigenous Australians reported living in dwellings of an unacceptable standard (Table 2.02.6).

Major structural problems: In 2014–15 in New South Wales, 28% of Indigenous Australians reported living in dwellings with major structural problems, compared with 15% of non-Indigenous Australians. The most common structural problems were major cracks in walls/floors (11.4%).

Nationally, 26% of Indigenous Australians reported living in dwellings with major structural problems, compared with 14% of non-Indigenous Australians. The most common structural problems were major cracks in walls/floors (10.5%) (Table 2.02.1, Figure 2.02.1).

Access to household facilities: In 2014–15 in New South Wales, 3.1% of Indigenous Australians reported they did not have access to facilities for washing people; 6.6% did not have access to facilities for washing clothes and bedding; 7.0% did not have access to facilities for preparing food; and 3.2% did not have access to working sewerage facilities.

Nationally, 3.3% of Indigenous Australians reported they did not have access to facilities for washing people; 8.7% did not have access to facilities for washing clothes and bedding; 8.0% did not have access to facilities for preparing food; and 3.5% did not have working sewerage facilities (Table 2.02.3, Figure 2.02.2).

Trend over time: Between 2008 and 2014–15 in New South Wales, the proportion of Indigenous Australians reported living in dwellings of an unacceptable standard varied between 22% and 17%.

Nationally, between 2008 and 2014–15, the proportion of Indigenous Australians who reported living in dwellings of an unacceptable standard also varied between 22% and 17% (Table 2.02.6, Figure 2.02.3).
Figure 2.02.1: Proportion of Indigenous households with major structural problems, New South Wales and Australia, 2014–15

Figure 2.02.2: Proportion of Indigenous households without working facilities to support healthy living, New South Wales and Australia, 2014–15

Figure 2.02.3: Proportion of Indigenous households in houses of an unacceptable standard, New South Wales and Australia, 2008, 2012–13 and 2014–15

Why it is important

This measure reports Indigenous children aged 0–14 who live in households with daily smokers and daily indoor smokers. Environmental tobacco smoke (also known as second-hand smoke) is a significant cause of morbidity and mortality. There is strong and consistent evidence that second-hand smoke causes lung cancer and ischaemic heart disease, and is associated with an increased risk of respiratory disease in adults. It increases the risk of sudden infant death syndrome and exacerbates asthma and ear infections such as otitis media in children (Thomas & Stevens 2014). Exposure to second-hand smoke during pregnancy is associated with an increased risk in neural tube defects (Wang et al. 2014a).

Key findings

**Overall:** In New South Wales in 2014–15, 52% of Indigenous children aged 0–14 were reported to live in households with daily smokers, compared with 20% of non-Indigenous children (Table 2.03.3, Figure 2.03.1). Of all Indigenous children, 15% lived in households where smoking occurred indoors (Table 2.03.4, Figure 2.03.2).

Nationally, 57% of Indigenous children aged 0–14 were reported to live in households with daily smokers, compared with 21% of non-Indigenous children (Table 2.03.3, Figure 2.03.1). Nationally, 13% of Indigenous children lived in households where smoking occurred indoors (Table 2.03.4; Figure 2.03.2).

**Remoteness:** Nationally, in 2014–15, the proportion of Indigenous children living in households with a daily smoker was reported to be highest for those in Very remote areas (76% and 49%). For non-Indigenous children, the proportion was highest in Outer regional areas and lowest in Major cities (32% and 18%) (Table 2.03.5). Data are not available for non-Indigenous children in Very remote areas.

Nationally, the rate of indoor smoking was highest for Indigenous children living in Very remote areas (20%) and Inner regional areas (14%), and lowest for those living in Major cities (11%) (Table 2.03.6).

**Socioeconomic characteristics:** Nationally, in 2014–15, 49% of Indigenous children living with regular daily smokers were reported to be from households with an income in the lowest quintile. The proportion of Indigenous children living in households with the lowest income quintile households, were exposed to smoking indoors at 6.6 times the proportion for those living in households with an income in the highest 2 income quintiles (19% compared with 3%). Of Indigenous children living with regular daily smokers, 82% lived in a rented household, and 29% lived in overcrowded homes (Table 2.03.8).

**Trend over time:** Nationally, the proportion of Indigenous children who were reported to live in a household with a daily smoker fell from 68% in 2004–05 to 57% in 2014–15. For non-Indigenous children the proportion fell from 35% in 2004–05 to 21% in 2014–15 (Table 2.03.7, Figure 2.03.3).

2.04 Literacy and numeracy

Why it is important

This measure reports on Year 3, 5, 7 and 9 students achieving national benchmarks.

Key findings

Reading: In New South Wales in 2016, 88% of Indigenous students met or exceeded the Year 3 national minimum standard for reading, 79% for Year 5, 85% for Year 7, and 80% for Year 9. For non-Indigenous students, the proportions were 96% for Year 3, 94% for Year 5, 96% for Year 7 and 94% for Year 9.

Nationally, 81% of Indigenous students met or exceeded the Year 3 national minimum standard in reading, 71% for Year 5, 77% for Year 7, and 74% for Year 9. For non-Indigenous students, the proportions were 96% for Year 3, 94% for Year 5, 96% for Year 7 and 94% for Year 9 (Table 2.04.1, Figure 2.04.1).

Writing: In New South Wales in 2016, 92% of Indigenous students met or exceeded the Year 3 national minimum standard for writing, 82% for Year 5 students, 71% for Year 7, and 58% for Year 9. For non-Indigenous students, the proportions were 98% for Year 3, 95% for Year 5, 91% for Year 7 and 84% for Year 9.

Nationally, 85% of Indigenous students met or exceeded the national minimum standard for writing in Year 3, 74% for Year 5, 64% for Year 7, and 53% for Year 9. For non-Indigenous students, the proportions were 97% for Year 3, 94% for Year 5, 91% for Year 7 and 85% for Year 9 (Table 2.04.3, Figure 2.04.1).

Spelling: In New South Wales in 2016, 85% of Indigenous students met or exceeded the Year 3 national minimum standard for spelling, 80% for Year 5, 81% for Year 7, and 77% for Year 9. For non-Indigenous students, the proportions were 96% for Year 3, 94% for Year 5, 95% for Year 7 and 93% for Year 9.

Nationally, 78% of Indigenous students met the standard for Year 3, 74% for Year 5, 75% for Year 7, and 70% for Year 9. For non-Indigenous students, the proportions were 95% for Year 3, 94% for Year 5, 94% for Year 7, and 92% for Year 9 (Table 2.04.5, Figure 2.04.2).

Grammar and punctuation: In New South Wales in 2016, 89% of Indigenous students met or exceeded the Year 3 national minimum standard for grammar and punctuation, 82% for Year 5, 77% for Year 7, and 75% for Year 9. For non-Indigenous students, the proportions were 97% for Year 3, 95% for Year 5, 94% for Year 7 and 92% for Year 9.

Nationally, 82% of Indigenous students met or exceeded the national minimum standard for Year 3, 74% for Year 5, 70% for Year 7, and 67% for Year 9. For non-Indigenous students, the proportions were 96% for Year 3, 95% for Year 5, 94% for Year 7 and 92% for Year 9 (Table 2.04.7, Figure 2.04.2).

Numeracy: In New South Wales in 2016, 88% of Indigenous students met or exceeded the Year 3 national minimum standard for numeracy, 83% for Year 5, 85% for Year 7, and 84% for Year 9. For non-Indigenous students, the proportions were 96% for all Years.

Nationally, 83% of Indigenous students met or exceeded the standard for numeracy in Year 3, 76% for Year 5, 79% for Year 7, and 80% for Year 9. For non-Indigenous students, the proportions were around 96% for Years 3, 5, and 9, and 97% for Year 7 (Table 2.04.9, Figure 2.04.3).
Figure 2.04.1: Proportion of Indigenous students in Years 3, 5, 7, 9 at or above the national minimum standard for reading and writing, New South Wales and Australia, 2016

Figure 2.04.2: Proportion of Indigenous students in Years 3, 5, 7, 9 at or above the national minimum standard for spelling, and grammar and punctuation, New South Wales and Australia, 2016

Figure 2.04.3: Proportion of Indigenous students in Years 3, 5, 7, 9 at or above the national minimum standard for numeracy, New South Wales and Australia, 2016

2.05 Education outcomes for young people

Why it is important

This measure reports on the rates of Indigenous students who stay in education through Year 10 and Year 12, as well as Indigenous students Year 12 attainment rates. Higher levels of education are associated with better health outcomes through greater health literacy as well as better prospects for socioeconomic status (including income and employment), which supports better access to safe and healthy housing, as well as healthy lifestyle choices such as regularly eating fruit and vegetables, and not smoking (Clark & Utz 2014).

Research in the US found that mortality declined at a faster pace for those with more education, with a 7-year increase in life expectancy for college-educated students (Wong et al. 2002). International literature also documents that increased levels of maternal education leads to lower child mortality, due to various factors, including a better understanding of health services and a greater willingness to access them.

Key findings

**Apparent retention:** In New South Wales in 2015, the apparent retention rate from Year 7/8 to Year 12 was 52% for Indigenous students, and 80% for other students. The apparent retention rate from Year 10 to Year 12 was 49% for Indigenous students, and 79% for other students.

Nationally, the apparent retention rate from Year 7/8 to Year 12 was 59% for Indigenous students, and 85% for other students. The apparent retention rate from Year 10 to Year 12 was 61% for Indigenous students, and 84% for other students (Table 2.05.2, Figure 2.05.1).

**School attendance:** In New South Wales in 2014–15, 97% of Indigenous children aged 4–14 were reported to usually attend school (Table 2.05.10, Figure 2.05.2), and 27% had missed days at school, preschool, or kindergarten in the week before the survey. Nationally, 96% of Indigenous children aged 4–14 were reported to usually attend school (Table 2.05.10, Figure 2.05.2), and 28% had missed days at school, preschool, or kindergarten in the week before the survey (Table 2.05.10).

**Unfairness:** In New South Wales in 2014–15, 8.2% of Indigenous children aged 2–14 were reported to have been treated unfairly at school. This included the current school or previous schools the child had attended.

Nationally, 8.7% of Indigenous children aged 2–14 were reported to have been treated unfairly at school (Table 2.05.13).

**Year 12 or equivalent:** In New South Wales in 2014–15, 63% of Indigenous Australians aged 20–24 reported they had attained Year 12 or equivalent, or Certificate II or above, and 51% had attained Year 12 or equivalent, or Certificate III or above. For non-Indigenous Australians, the proportions were 87% and 86% respectively.

Nationally, 62% of Indigenous Australians aged 20–24 reported they had attained Year 12 or equivalent, or Certificate II or above, 54% had attained Year 12 or equivalent, or Certificate III or above. For non-Indigenous Australians, the proportions were 86% and 85% (Table 2.05.14, Figure 2.05.3).

2.06 Educational participation and attainment of adults

Why it is important

This measure reports on educational participation by adults (undertaking formal education or training) and educational attainment (completion of a particular level of school education or non-school qualification). Adult learning is a powerful tool in achieving better health, education and economic outcomes (Chandola & Jenkins 2014). The employment gap between Indigenous and non-Indigenous Australians declines as the level of education attainment increases. The transition from education to work is usually smoother for vocational education and training (VET) and university graduates, and salaries are higher than for those who enter the workforce directly from school (Lamb & McKenzie 2001).

Key findings

Overall: In New South Wales in 2014–15, 26% of Indigenous Australians aged 15 and over reported that they were currently studying at an educational institution, compared with 17% of non-Indigenous Australians. Of those who were studying, the highest proportion of Indigenous and non-Indigenous students were at an institution for technical or further education (39% and 36%, respectively).

Nationally, 22% of Indigenous Australians aged 15 and over reported that they were currently studying at an educational institution, compared with 18% of non-Indigenous Australians. Of those who were studying, the highest proportion of Indigenous students (36%) were at secondary school, but the highest proportion of non-Indigenous students were studying at a university or other higher education institution (39%) (Table 2.06.3, Figure 2.06.1).

Highest level of school completed: In New South Wales in 2014–15, 25% of Indigenous adults (aged 18 and over) reported that Year 12 or equivalent was the highest level of school completed, compared with 56% of non-Indigenous adults.

Nationally, 28% of Indigenous adults (aged 18 and over) reported that Year 12 or equivalent was the highest level of school completed, compared with 58% of non-Indigenous adults (Table 2.06.7, Figure 2.06.2).

Non-school qualification: In New South Wales in 2014–15, 51% of Indigenous Australians aged 20–64 reported they either had a Certificate III or above, or were studying at any level, compared with 69% of non-Indigenous Australians.

Nationally, 47% of Indigenous Australians aged 20–64 reported they either had a Certificate III or above, or were studying at any level, compared with 70% of non-Indigenous Australians (Table 2.06.11, Figure 2.06.3).

Trend over time: Nationally, the proportion of Indigenous Australians aged 15 and over who reported that they were currently studying rose from 18% in 2002 to 22% in 2014–15. This included studying at secondary schools, institutions for technical or further education, and universities or other higher education institutions (Table 2.06.20).
Figure 2.06.1: Proportion of Australians (aged 15 and over) who were currently studying, by Indigenous status, New South Wales and Australia, 2014–15

Figure 2.06.2: Proportion of adults (aged 18 and over) who had completed Year 12, by Indigenous status, New South Wales and Australia, 2014–15

Figure 2.06.3: Proportion (aged 20–64) whose highest level of non-school qualification was Certificate III or above and/or who were currently studying, by Indigenous status, New South Wales and Australia, 2014–15

2.07 Employment

Why it is important

This measure reports on the employment status of Indigenous Australians aged 15–64. Participation in employment has important consequences for health, social and emotional wellbeing and living standards for individuals, families and communities (Bambra 2011; Gray et al. 2014). Conversely, being sick or disabled, or looking after someone in poor health acts as a barrier to labour force participation (Belachew & Kumar 2014). Health risks from being unemployed include mental health and stress related health impacts such as heart disease (Wilkinson & Pickett 2009), being unable to afford necessities such as food, security, safe neighbourhoods and adequate housing (Bambra 2011), and the effects from adopting unhealthy coping behaviours (Dooley et al. 1996). Experiencing extended and repeated periods of unemployment compound these effects (Taulbut et al. 2013).

Key findings

Labour force participation: In New South Wales in 2014–15, 62% of Indigenous Australians of working age (15–64) reported they were in the labour force, compared with 76% of non-Indigenous Australians (in 2014).

Nationally, 61% of Indigenous Australians of working age (15–64) reported they were in the labour force, compared with 77% of non-Indigenous Australians (Table 2.07.5, Figure 2.07.1). The largest difference between Indigenous and non-Indigenous Australians in the labour force was for those aged 45–54, where the proportions were 59% compared with 84% (Table 2.07.3).

Employment: In New South Wales in 2014–15, 53% of the Indigenous working-age population reported they were employed (Table 2.07.5, Figure 2.07.2), with 32% working full time, and 21% working part time (Table 2.07.5). For non-Indigenous Australians in 2014, 71% of the working-age population were employed (Table 2.07.5, Figure 2.07.2), with 51% working full time, and 20% working part time (Table 2.07.5).

Nationally, 48% of the Indigenous working-age population reported they were employed (Table 2.07.5, Figure 2.07.2), with 29% working full time, and 19% working part time (Table 2.07.5). For non-Indigenous Australians, 73% of the working-age population were employed (Table 2.07.5, Figure 2.07.2), with 51% working full time, and 21% working part time (Table 2.07.5).

Unemployment: In 2014–15 in New South Wales, the reported unemployment rate for Indigenous Australians was 9.5%, compared with 4.3% for non-Indigenous Australians (in 2014).

Nationally, the reported unemployment rate for Indigenous Australians was 12.7%, compared with 4.5% for non-Indigenous Australians (Table 2.07.5, Figure 2.07.3).

Difficulty in finding work: Nationally, 92% of Indigenous Australians who were unemployed reported difficulties in finding work. The most common reasons provided were that there were no jobs in the local area or line of work (41%), and problems with transport or distance (32%) (Table 2.07.10).

2.08 Income

Why it is important

This measure reports on equivalised gross household and individual income. Studies across different countries have found a gradient in health outcomes associated with income (Marmott 2002). Income itself is highly correlated with educational attainment, employment and various social indicators (Deaton 2003). The relationship between income and health is complex, and is linked to other factors such as the capacity to live a healthy life, including being able to afford nutritious food and quality housing (AHMAC 2017).

Key findings

Equivalised gross weekly household income: In New South Wales in 2014–15, one-third (33%) of Indigenous adults (aged 18 and over) reported they were living in households in the lowest equivalised weekly household income quintile. This was about twice the proportion for non-Indigenous adults (17%) (Table 2.08.1, Figure 2.08.1). 3.1% of Indigenous adults lived in households with a weekly income in the highest quintile, compared with 21% of non-Indigenous Australians (Table 2.08.1).

Nationally, more than one-third (37%) of Indigenous adults reported they were living in households in the lowest income quintile. This was over twice the proportion for non-Indigenous adults (17%) (Table 2.08.1, Figure 2.08.1). 6.2% of Indigenous adults lived in households with a weekly income in the highest quintile, compared with 22% of non-Indigenous Australians (Table 2.08.1).

Median equivalised gross weekly household income: In New South Wales in 2014–15, the reported median equivalised gross weekly household income for Indigenous adults was $550, compared with $850 for non-Indigenous adults.

Nationally, the reported median equivalised gross weekly household income for Indigenous adults was $542, compared with $852 for non-Indigenous adults (Table 2.08.3).

Ability to raise $2,000 in a week: In New South Wales in 2014–15, 45% of Indigenous Australians reported they were living in households that could not raise $2,000 within a week in an emergency (indicating financial stress). The rate was higher in Remote areas (61%) than Non-remote areas (44%).

Nationally, 50% of Indigenous Australians reported they were living in households that could not raise $2,000 within a week in an emergency. The rate was higher in Remote areas (64%) than Non-remote areas (46%) (Table 2.08.6, Figure 2.08.2).

Trend over time: In New South Wales, the reported median equivalised gross weekly household income (in 2014–15 dollars) for people aged 18 and over rose significantly, from $412 in 2002 to $550 in 2014–15 for Indigenous Australians. For non-Indigenous Australians, it rose from $808 in 2002 to $930 in 2012–13, and then fell to $850 in 2014–15.

Nationally, the reported median equivalised gross weekly household income for adults rose significantly from $402 in 2002 to $542 in 2014–15 for Indigenous Australians. For non-Indigenous Australians, it rose from $751 in 2002 to $907 in 2012–13, and then fell to $852 in 2014–15 (Table 2.08.3, Figure 2.08.3).

Figure 2.08.3: Median equivalised gross weekly household income of adults (aged 18 and over), by Indigenous status, New South Wales and Australia, 2002 to 2014–15

2.09 Index of disadvantage

Why it is important

This measure reports on the relative disadvantage for Indigenous Australians compared with non-Indigenous Australians. It is based on the Index of Relative Socio-Economic Advantage and Disadvantage (SEIFA), and shows the distribution of the Indigenous population across areas of advantage and disadvantage. The areas are grouped into quintiles (5 categories of advantage or disadvantage, with 1 being the lowest socioeconomic status (SES) and 5 being the highest SES) under the Socio-Economic Indexes for Areas (SEIFA). Results from the 2011 Census showed that Indigenous Australians had higher levels of socioeconomic disadvantage than non-Indigenous Australians across all remoteness areas. In Australia, there were no areas where the Indigenous population had greater or equal economic outcomes compared with the non-Indigenous population (Biddle 2013).

Key findings

Overall: In New South Wales in 2011 half (51%) of the total Indigenous population lived in the most disadvantaged areas (quintile 1), however 5% lived in areas of most advantage (quintile 5). For non-Indigenous Australians, 21% of the population lived in the most disadvantaged areas, and 24% lived in areas of most advantage (quintile 5).

Nationally, the distribution of Indigenous Australians was similar, almost half (52%) of the total Indigenous population living in the most disadvantaged areas (quintile 1), and 5% living in areas of most advantage (quintile 5). The proportions for non-Indigenous Australians were 19% in the most disadvantaged areas (quintile 1) and 21% in least disadvantaged areas (quintile 5) (Table 2.09.2, Figure 2.09.1).

Source: Table 2.09.2.

Figure 2.09.1: Population distribution, by SEIFA advantage/disadvantage quintiles, by Indigenous status, New South Wales and Australia, 2011

This page is left intentionally blank.
2.10 Community safety

Why it is important

This measure reports on experience of personal injury or death as a result of violence, threatened violence or a social setting in which violence is common, and social settings where there is a lack of security and a perception of danger (AHMAC 2015). The level of violence experienced by Indigenous Australians is also experienced in a context of discrimination and markers of disadvantage such as low income, unemployment and substance abuse (Day et al. 2013).

Key findings

Feeling safe: In New South Wales in 2014–15, 67% of Indigenous Australians aged 15 and over reported they felt safe or very safe when they walked alone in the local area after dark, and 21% felt unsafe or very unsafe. At home, 87% felt safe or very safe, and 8% felt unsafe or very unsafe after dark.

Nationally, 68% of Indigenous Australians aged 15 and over reported they felt safe or very safe when they walked alone in the local area after dark, and 20% felt unsafe or very unsafe. At home, 87% felt safe or very safe, and 8% felt unsafe or very unsafe after dark (Table 2.10.2, Figure 2.10.1).

Neighbourhood or community problems: In New South Wales in 2014–15, 71% of Indigenous Australians aged 15 and over reported that they were aware of neighbourhood or community problems, 46% were aware of theft, 42% were aware of dangerous or noisy driving, 38% were aware of illegal drugs, 37% were aware of alcohol and 33% were aware of vandalism and property damage.

Nationally, 71% of Indigenous Australians aged 15 and over reported that they were aware of neighbourhood or community problems, 45% were aware of theft, 39% were aware of alcohol, 38% were aware of illegal drugs, 32% were aware of problems involving youths and 30% were aware of vandalism and property damage (Table 2.10.2, Figure 2.10.2).

Victims of violence: In New South Wales in 2014–15, the age-standardised rate for Indigenous Australians aged 18 and over reporting that they were a victim of physical or threatened violence in the previous 12 months was 20%, 2.4 times the rate for non-Indigenous Australians in 2014 (8.1%).

Nationally, the age-standardised rate for Indigenous Australians aged 18 and over reporting they were a victim of physical or threatened violence in the previous 12 months was 20%, 2.5 times the rate for non-Indigenous Australians (8.1%) (Table 2.10.25).

Trend over time: In New South Wales, the age-standardised rate of Indigenous Australians aged 18 and over reporting they were a victim of physical or threatened violence in the previous 12 months rose from 17% in 2002 to 20% in 2014–15. For non-Indigenous Australians, the rate rose from 8.5% in 2002 to 9.3% in 2008, then fell to 8.1% in 2014–15.

Nationally, the age-standardised rate of Indigenous Australians aged 18 and over reporting they were a victim of physical or threatened violence in the previous 12 months remained at 20% in 2002, 2008 and 2014–15. For non-Indigenous Australians, the rate was 8.9% in 2002, 10.8% in 2008, and 8.1% in 2014–15 (Table 2.10.25, Figure 2.10.3).
2.11 Contact with the criminal justice system

Why it is important

This measure reports on the prevalence of Indigenous Australians in prison custody, and those who have other contact with the criminal justice system, including police custody and juvenile justice. It also reports on relationships with health and social factors. Indigenous Australians experience higher rates of arrest and incarceration than non-Indigenous Australians. Imprisonment also affects family, children and the broader community. It increases stress, affects relationships and has adverse employment and financial consequences (AHMAC 2017).

Key findings

Youth justice supervision: In New South Wales on an average day in 2014–15, of Indigenous Australians aged 10–17, 149 per 10,000 were under youth justice supervision, compared with 10 per 10,000 for non-Indigenous Australians.

Nationally, of Indigenous Australians aged 10–17, 180 per 10,000 were under youth justice supervision, compared with 12 per 10,000 for non-Indigenous Australians (Table 2.11.1, Figure 2.11.1).

Prison custody: In New South Wales on 30 June 2016, 24% of people in prison custody were Indigenous. The age-standardised rate of Indigenous adults in prison custody was 11.3 times the rate for non-Indigenous Australians (1,992 compared with 176 per 100,000) (Table 2.11.8, Figure 2.11.2). The number of Indigenous males in prison custody was higher than Indigenous females (2,724 compared with 309). The number of non-Indigenous males in prison custody was also higher than the number of non-Indigenous females (8,951 compared with 632) (Table 2.11.8).

Nationally, 27% of people in prison custody were Indigenous. The age-standardised rate of Indigenous adults in prison custody was 12.5 times the rate for non-Indigenous Australians (2,039 compared with 163 per 100,000) (Table 2.11.8, Figure 2.11.2). For Indigenous Australians, the number of males in prison custody was 9 times the number of females (9,534 compared with 1,062). For non-Indigenous Australians, the number of males in prison custody was 13 times the number of females (26,190 compared with 2,033) (Table 2.11.8).

Trend over time: In New South Wales, the rate of young Indigenous Australians aged 10–17, who were under youth justice supervision on an average day rose from 145 per 10,000 in 2002–03 to 149 per 10,000 in 2014–15. The rate for non-Indigenous Australians fell from 12 to 10 per 10,000 (Table 2.11.1, Figure 2.11.1). The age-standardised imprisonment rate rose by 72% for Indigenous adults, from 1,084 per 100,000 in 2000 to 1,992 per 100,000 in 2016. For non-Indigenous adults, the rate rose by 4.5%, from 157 to 176 per 100,000, which was not statistically significant (Table 2.11.12, Figure 2.11.3).

Nationally, the rate of Indigenous young people aged 10–17 who were under youth justice supervision on an average day fell from 197 per 10,000 in 2006–07 to 180 per 10,000 in 2014–15. For non-Indigenous Australians, the rate fell by 18%, from 14 to 12 per 10,000 (Table 2.11.1, Figure 2.11.1). The age-standardised imprisonment rate for Indigenous adults rose from 1,100 per 100,000 in 2000 to 2,039 per 100,000 in 2016. For non-Indigenous adults the rate rose more slowly, from 129 to 163 per 100,000 (tables 2.11.1, 2.11.12, figures 2.11.1, 2.11.3).
Figure 2.11.1: Rate of young people (aged 10–17) under youth justice supervision on an average day, by Indigenous status, New South Wales and Australia, 2006–07 to 2014–15

Figure 2.11.2: Age-standardised adult imprisonment rate, by Indigenous status, New South Wales and Australia, 30 June 2016

Figure 2.11.3: Age-standardised adult imprisonment rate, by Indigenous status, New South Wales and Australia, 2000–2016

2.12 Child protection

Why it is important

This measure reports on the number and rate for children who were the subject of substantiated child protection notifications, on care and protection orders, and in out-of-home care.

Maltreatment (physical, emotional and psychological abuse, neglect, sexual abuse and witnessing family violence) during childhood has serious and long-term effects on social and emotional wellbeing and health (Emerson et al. 2015).

Key findings

Overall: In New South Wales in 2014–15, the rate for Indigenous children who were the subject of a substantiated child protection notification was 51 per 1,000, 7.9 times the rate for non-Indigenous children (6.4 per 1,000).

Nationally, the rate for Indigenous children who were the subject of a substantiated child protection notification was 40 per 1,000, 6.7 times the rate for non-Indigenous children (5.9 per 1,000) (Table 2.12.3, Figure 2.12.1).

Trend over time: In New South Wales, the rate for Indigenous children who were the subject of a substantiated child protection notification rose from 43 per 1,000 in 2008–09 to 51 per 1,000 in 2014–15.

Nationally, the rate for Indigenous children also rose, from 29 per 1,000 in 2008–09 to 40 per 1,000 in 2014–15 (Table 2.12.5, Figure 2.12.2).

Care and protection orders: In New South Wales on 30 June 2015, the rate for Indigenous children (aged 0–17) who were on care and protection orders was 72 per 1,000, 10 times the rate for non-Indigenous children (7.4 per 1,000).

Nationally, the rate for Indigenous children on care and protection orders was 58 per 1,000, 9 times the rate for non-Indigenous children (6.3 per 1,000) (Table 2.12.7, Figure 2.12.1).

Trend over time: In New South Wales the rate for Indigenous children who were on care and protection orders rose from 45 per 1,000 at 30 June 2009 to 72 per 1,000 at 30 June 2015. The rate for non-Indigenous children who were on care and protection orders increased from 6.2 per 1,000 at 30 June 2009 to 7.4 per 1,000 at 30 June 2015.

Nationally, the rate for Indigenous children on care and protection orders increased from 37 per 1,000 at 30 June 2009 to 58 per 1,000 at 30 June 2015. The rate for non-Indigenous children who were on care and protection orders increased from 5.3 per 1,000 at 30 June 2009 to 6.3 per 1,000 at 30 June 2015. (Table 2.12.11, Figure 2.12.3).

Out-of-home care: In New South Wales on 30 June 2015, the rate for Indigenous children in out-of-home care was 67 per 1,000 (Table 2.12.12, Figure 2.12.1), 10 times the rate for non-Indigenous children (6.6 per 1,000) (Table 2.12.12).

Nationally, the rate for Indigenous children in out-of-home care was 53 per 1,000, 10 times the rate for non-Indigenous children (5.5 per 1,000) (Table 2.12.12, Figure 2.12.1).
2.13 Transport

Why it is important

This measure reports on the use of transport, including walking, access to motor vehicles and perceived difficulty with transport for Indigenous Australians. Transport is key to enabling access to health care, goods and services, and supports Indigenous people to achieve education and employment outcomes and maintain cultural obligations to travel to family commitments (Helps et al. 2010; Ivers et al. 2016). Indigenous Australians face various barriers to accessing appropriate health care, including logistics, cost and reliability of transport options (Lee et al. 2014). Having limited or no public transport options significantly affects the capacity to access health care, particularly for patients with chronic health conditions (Teng et al. 2014) those needing birthing services (Parker et al. 2014), and those in rural and remote areas (Kelly et al. 2014).

Key findings

Overall: In New South Wales in 2014–15, 81% of Indigenous Australians aged 15 and over reported they could easily get to places as needed, compared with 84% for non-Indigenous Australians. An estimated 5% of Indigenous Australians reported that they were unable to get to places needed, never went out or were housebound, compared with 1% for non-Indigenous Australians.

Nationally, 75% of Indigenous Australians aged 15 and over reported they could easily get to places as needed, compared with 84% for non-Indigenous Australians. An estimated 8% of Indigenous Australians reported that they were unable to get to places as needed, never went out or were housebound, compared with 1% for non-Indigenous Australians (Table 2.13.4, Figure 2.13.1).

Access to a motor vehicle: In New South Wales in 2014–15, 79% of Indigenous Australians aged 15 and over reported that they had access to a motor vehicle, 0.9 times the proportion for non-Indigenous Australians (84%).

Nationally, 75% of Indigenous Australians aged 15 and over reported that they had access to a motor vehicle, also 0.9 times the proportion for non-Indigenous Australians (85%) (Table 2.13.8, Figure 2.13.2).

Use of public transport: In New South Wales in 2014–15, 29% of Indigenous Australians aged 15 and over who were not housebound, reported that they had used public transport in the previous 2 weeks.

Nationally, 29% of Indigenous Australians who were not housebound reported they had used public transport in the previous 2 weeks (Table 2.13.9).

Access to public transport: In New South Wales in 2014–15, public transport was available to 86% of Indigenous Australians aged 15 and over. Of those who could access it, 82% reported they preferred to use their own transport or walk.

Nationally, public transport was available to 75% of Indigenous Australians aged 15 and over. Of those who could access it, 79% reported they preferred to use their own transport or walk (Table 2.13.10, Figure 2.13.3).
Figure 2.13.1: Proportion of Australians (aged 15 and over) perceived level of difficulty with transport, by Indigenous status, New South Wales and Australia, 2014–15

Figure 2.13.2: Proportion of Australians’ (aged 15 and over) with access to a motor vehicle, by Indigenous status, New South Wales and Australia, 2014–15

Figure 2.13.3: Proportion of Indigenous adults (aged 18 and over) who did not use public transport in the previous 2 weeks in local areas where public transport was available, by reasons, New South Wales and Australia, 2014–15

2.14 Indigenous people with access to their traditional lands

Why it is important
This measure reports on the proportion of Indigenous Australians living on or visiting traditional areas of land with which they have ancestral or cultural links. Connection to family and community, land and sea, and cultural identity are integral to health from an Aboriginal perspective (NAHSWP 1989). Ongoing access to traditional lands also offers socio-political, economic and environmental benefits (Weir et al. 2011). Access to traditional lands is a determinant of health in remote contexts where Indigenous Australians are more likely to have ownership and control over their Country; it is also a determinant of health for those living in non-remote and urban areas. Research in Victoria has found the role of Country helps strengthen self-esteem, self-worth, pride, cultural and spiritual connection, and positive states of wellbeing (Kingsley et al. 2013).

Key findings
Overall: In New South Wales in 2014–15, 70% of Indigenous Australians aged 15 and over reported that they recognised homelands or traditional Country. Nationally, 74% of Indigenous Australians aged 15 and over reported that they recognised homelands or traditional Country (Table 2.14.6). The proportion was higher in Remote than in Non-remote areas (89% compared with 70%) (Table 2.14.1, Figure 2.14.1).

Living on homelands or traditional Country: In New South Wales in 2014–15, 26% of Indigenous Australians aged 15 and over reported that they lived on their homelands or traditional Country. Nationally, 23% of Indigenous Australians aged 15 and over reported that they lived on their homelands or traditional Country (Table 2.14.6, Figure 2.14.2).

Visiting homelands or traditional Country: In New South Wales in 2014–15, 41% of Indigenous Australians aged 15 and over reported that they were allowed to visit their homelands or traditional Country, and less than 1% reported they were not allowed to visit. Nationally, a higher proportion of Indigenous Australians were allowed to visit their homelands or traditional Country than the proportion in New South Wales (50% compared with 41%) and 1% reported not being allowed to visit (Table 2.14.6, Figure 2.14.2).

Identifying with clan, tribal or language group: In New South Wales in 2014–15, a higher proportion of Indigenous Australians aged 15 and over reported that they identified with a clan, tribal group, or language group (55%). The proportion that didn’t identify was 45%. Nationally, the proportion of Indigenous Australians aged 15 and over who reported that they identified with a clan, tribal group, or language group was higher than the proportion for New South Wales (62% compared with 55%) (Table 2.14.6, Figure 2.14.3).
2.15 Tobacco use

Why it is important

This measure reports on the proportion of Indigenous Australians who smoke daily, at least once a week and less than weekly. The health impact of smoking is evident in the high rates of hospitalisation and deaths from tobacco-related conditions (for example, chronic lung disease, cardiovascular disease and many forms of cancer) (Marley et al. 2014; Pircher et al. 2012). Maternal smoking during pregnancy increases the risk of poor outcomes for babies and children. Second-hand smoke also has adverse health effects for those exposed to it (AHMAC 2017).

Key findings

Overall: In New South Wales in 2014–15, the age-standardised rate for Indigenous Australians aged 15 and over reporting to be a current smoker was 40%, 28% were ex-smokers and 32% had never smoked. Nationally, the age-standardised rate for Indigenous Australians aged 15 and over reporting to be a current smoker was 42%, 26% were ex-smokers and 32% had never smoked (Table 2.15.7, Figure 2.15.1).

Remoteness: Nationally the age-standardised rate for Indigenous Australians aged 15 and over reporting to be a current smoker was higher in Remote areas than in Non-remote areas by 11 percentage points (51% compared with 40%). The rate of non-Indigenous Australians who were current smokers was also higher in Remote areas than in Non-remote areas (19% compared with 15%), a 4 percentage point difference (Table 2.15.8).

Current smokers: In New South Wales in 2014–15, the age-standardised rate for Indigenous Australians aged 15 and over reporting to be a current smoker was 2.6 times the rate for non-Indigenous current smokers (40% compared with 15%). Nationally, the age-standardised rate for Indigenous Australians aged 15 and over reporting to be a current smoker was 2.7 times the rate for non-Indigenous Australians (42% compared with 15%) (Table 2.15.7, Figure 2.15.2).

Quitting status: In New South Wales in 2014–15, more than two-thirds (68%) of Indigenous Australians aged 15 and over who reported being a current smoker reported they had tried to quit or reduce smoking. Nationally, the proportion was similar, with 69% of Indigenous Australians who reported being a current smoker had tried to quit or reduce smoking (Table 2.15.10).

Trend over time: In New South Wales, the rate of Indigenous Australians aged 15 and over that reported being a current smoker fell from 53% in 1994 to 40% in 2014–15. Nationally the rate of Indigenous Australians aged 15 and over that reported being a current smoker fell from 52% in 1994 to 42% in 2014–15 (Table 2.15.1, Figure 2.15.3).

Figure 2.15.2: Proportion of current smokers (aged 15 and over), by Indigenous status, New South Wales and Australia, 2014–15

Figure 2.15.3: Proportion of current smokers, Indigenous Australians (aged 15 and over), New South Wales and Australia, 1994 to 2014–15

2.16 Risky alcohol consumption

Why it is important
This measure reports on the consumption of alcohol at risky or high-risk levels. Excessive consumption is associated with health and social problems in most populations. Long-term excessive consumption is a major risk factor for conditions such as liver disease, pancreatitis, heart disease, stroke, diabetes, obesity and cancer. Binge drinking contributes to injuries, suicide, transport accidents, violence, burns and falls (AHMAC 2017).

Key findings
Non-Indigenous comparisons for single occasion and lifetime risk are not available for 2014–15, as the data were not collected as part of the ABS General Social Survey 2014.

Single occasion risk: In New South Wales in 2014–15, an estimated 30% of Indigenous Australians aged 15 and over reported exceeding the single occasion alcohol risk guidelines in the last 12 months.

Nationally, an estimated 31% of Indigenous Australians aged 15 and over reported exceeding the single occasion alcohol risk guidelines in the last 12 months (Table 2.16.19, Figure 2.16.1).

Lifetime risk: In New South Wales in 2014–15, an estimated 17% of Indigenous Australians aged 15 and over reported exceeding the lifetime risk alcohol guidelines.

Nationally, an estimated 15% of Indigenous Australians aged 15 and over reported exceeding the lifetime risk alcohol guidelines (Table 2.16.20, Figure 2.16.1).

Remoteness: In New South Wales in 2012–13, the age-standardised rate of Indigenous Australians aged 18 and over who reported that they had engaged in short-term or single occasion risky drinking was 53% in Non-remote areas, compared with 43% of non-Indigenous Australians. In Remote areas the rate was higher for Indigenous Australians and lower for non-Indigenous Australians (68% and 28%, respectively).

Nationally, the age-standardised rate of Indigenous Australians aged 18 and over who reported that they had engaged in short-term or single occasion risky drinking was 53% in Non-remote areas, compared with 45% of non-Indigenous Australians. In Remote areas the rate was lower for Indigenous Australians and higher for non-Indigenous Australians (47% and 55%, respectively) (Table 2.16.2, Figure 2.16.2).

Trend over time: In New South Wales, the age-standardised rate of hospitalisation related to alcohol use for Indigenous Australians fell from 7.9 per 1,000 in 2004–05 to 6.1 per 1,000 in 2014–15. For non-Indigenous Australians, the rate rose from 2.0 to 2.6 per 1,000.

For NSW, Vic, Qld, WA, SA and the NT combined, the age-standardised rate of hospitalisation related to alcohol use for Indigenous Australians rose from 7.2 per 1,000 in 2004–05 to 9.0 per 1,000 in 2014–15. For non-Indigenous Australians the rate rose from 1.9 to 2.3 per 1,000 over the same period (Table 2.16.13 NSW, Figure 2.16.3).

2.17 Drug and other substance use including inhalants

Why it is important
This measure reports on the use of drugs and other substances, including inhalants. Drug and other substance use is a contributing factor to illness and disease, accident and injury, violence and crime, family and social disruption and workplace problems (SCRGSP 2014). Substance use is often associated with mental health problems (Catto & Thomson 2008) and has been found to be a factor in suicides (Robinson et al. 2011). For communities, there is increased potential for social disruption, such as domestic violence, crime and assaults (Franks 2006). Alcohol and substance use has been found to be a factor in assault (Mitchell, 2011; Mouzos & Makkai 2004). Risky sexual behaviour is also associated with alcohol and illicit drug use, leading to increased sexually transmitted infections among younger people (Wand et al. 2016). Drugs and other substance use play a significant role in Indigenous people’s involvement in the criminal justice system (AHMAC 2017).

Key findings
Non-Indigenous comparisons for substance use are not available for 2014–15, as the data were not collected as part of the ABS General Social Survey 2014.

Overall: In New South Wales in 2014–15, an estimated 31% of Indigenous Australians aged 15 and over reported using substances in the last 12 months. Substance use was more prevalent for Indigenous males than females (32% compared with 29%).

Nationally, an estimated 31% of Indigenous Australians aged 15 and over reported using substances in the last 12 months. The proportion was higher for Indigenous males than females (34% compared with 27%, respectively) (Table 2.17.3, Figure 2.17.1).

Hospitalisations: Nationally, between July 2013 and June 2015, the age-standardised hospitalisation rate related to drug use was higher for Indigenous Australians who lived in Major cities than in other areas of Australia (8.1 per 1,000). The rate was 3.6 times the rate for non-Indigenous Australians in Major cities (2.3 per 1,000) (Table 2.17.8).

Use during pregnancy: In New South Wales in 2014–15, an estimated 3% of mothers of Indigenous children aged 0–3 reported illicit drug or substance use during pregnancy.

Nationally, the rate was slightly higher, with 4% of mothers reporting the use of illicit drugs or substances during pregnancy (Table 2.17.13, Figure 2.17.2).

Police detainees: In 2015, in selected police stations in Sydney (Bankstown and Surry Hills), 90% of Indigenous detainees (10 detainees) who provided a urine sample tested positive to a drug. The rate for non-Indigenous detainees (46 detainees) was 72% (Table 2.17.10).

Trend over time: In New South Wales between 2004 and 2015, the rate of detainees who provided urine during selected state collections and tested positive to a drug fluctuated between 67% and 92%. The rate for non-Indigenous detainees varied between 51% and 77% (Table 2.17.12, Figure 2.13.3).

There are no national data for urine analysis test results for detainees over time, as data are only collected in Adelaide, Sydney, Brisbane and Perth.

Aboriginal and Torres Strait Islander Health Performance Framework 2017: New South Wales 103
2.18 Physical activity

Why it is important

This measure reports on the levels of physical activity among Indigenous Australians (low, moderate or high). Physical activity can be defined as a bodily movement produced by the muscles resulting in energy expenditure, and can include organised or incidental activity (AIHW 2010a). Physical inactivity is an important modifiable risk factor associated with several potentially preventable chronic diseases that are prevalent among Indigenous Australians. These diseases include cardiovascular disease, cancer, stroke, hypertension, and diabetes (AIHW 2012; Gray et al. 2013; Wilmot et al. 2012). Physical inactivity is also related to being overweight and obese, another important risk factor for multiple preventable diseases (AHMAC 2017).

Results for adults are presented by whether a person (aged 18–64) had met the recommended guidelines for sufficient physical activity to gain a health benefit (150–300 minutes of moderate activity per week, or 75–150 minutes of vigorous activity per week) (ABS 2016). For children, results are presented in terms of time taken for physical activity and the number of days children were active.

Key findings

**Adult physical activity:** In *Non-remote* areas of New South Wales in 2012–13, 36% of Indigenous adults reported they had done enough physical activity for health in the previous week. The age-standardised rate for Indigenous adults who met sufficient activity levels in the last week was 0.7 times the rate for non-Indigenous adults (33% compared with 45%) (ABS 2014b).

Nationally in *Non-remote* areas, 38% of Indigenous adults reported they had done enough physical activity for health in the previous week. The age-standardised rate for Indigenous adults who met sufficient activity levels in the previous week was 0.8 times the rate for non-Indigenous adults (35% compared with 43%) (ABS 2014b, Figure 2.18.1).

**Children’s daily activity:** In New South Wales in 2014–15, 73% of Indigenous children aged 4–14 were reported to have done at least 60 minutes of physical activity every day, compared with 68% in 2008.

Nationally, 76% of Indigenous children aged 4–14 were reported to have done at least 60 minutes of physical activity every day, compared with 74% in 2008 (Table 2.18.3, Figure 2.18.2).

**Days of physical activity:** In New South Wales in 2014–15, 73% of Indigenous children aged 4–14 were reported to be physically active every day of the previous week, and 13% were active on 4–6 days. Almost 4% had days where they had not been active for any day in the previous week.

Nationally, 76% of Indigenous children aged 4–14 were reported to be physically active every day of the previous week, and 13% were active on 4–6 days. Almost 3% had days where they had not been active in the previous week (Table 2.18.2, Figure 2.18.3).

2.19 Dietary behaviour

Why it is important

This measure reports on dietary behaviour, including fruit and vegetable consumption. Many of the principal causes of ill-health among Indigenous Australians are nutrition-related diseases, such as heart disease, type 2 diabetes and renal disease. While a diet high in saturated fats and refined carbohydrates increases the likelihood of developing these diseases, regular exercise and intake of fibre-rich foods, such as fruit and vegetables, can have a protective effect against disease (Wang et al. 2014b).

Key findings

Consumption of fruit: In New South Wales in 2014–15, 27% of Indigenous Australians (aged 12 and over) reported eating less than 1 serve of fruit a day. This differed by remoteness area, with more Indigenous Australians in Remote than Non-remote areas reported eating less than 1 serve (40% compared with 27%).

Nationally, 25% of Indigenous Australians aged 12 and over reported eating less than 1 serve of fruit a day. The rate for Indigenous Australians living in Non-remote areas was similar to the rate for those living in Remote areas (25% and 24% respectively) (Table 2.19.2, Figure 2.19.1).

Consumption of vegetables: In New South Wales in 2014–15, 11% of Indigenous Australians (aged 12 and over) reported eating less than 1 serve of vegetables a day. This differed by remoteness, more Indigenous Australians in Remote than Non-remote areas reported eating less than 1 serve (20% compared with 11%).

Nationally, 12% of Indigenous Australians aged 12 and over reported eating less than 1 serve of vegetables per day. The proportion was lower in Non-remote than in Remote areas (11% compared with 15%) (Table 2.19.3, Figure 2.19.2).

Children’s consumption of fruit: In New South Wales in 2014–15, one-third (33%) of Indigenous children aged 2–14 were reported to eat 1 or less than 1 serve of fruit a day.

Nationally one-third (33%) of Indigenous children aged 2–14 were reported to eat 1, or less than 1 serve of fruit a day (Table 2.19.9, Figure 2.19.3).

Children’s consumption of vegetables: In New South Wales in 2014–15, 38% of Indigenous children aged 2–14 were reported to eat 1, or less than 1 serve of vegetables a day. Almost 29% were reported to eat 2 serves and 31% ate 3 or more. Almost 3% were reported to not usually eat vegetables.

Nationally, 39% of Indigenous children aged 2–14 were reported to eat 1, or less than 1 serve of vegetables a day, 30% ate 2 serves and 28% ate 3 or more. An estimated 3% were reported to not usually eat vegetables (Table 2.19.9, Figure 2.19.3).

2.20 Breastfeeding practices

Why it is important

This measure reports on the breastfeeding status of infants, including: breastfeeding duration; breastfeeding and other sources of food; and the reasons mothers stopped breastfeeding. Breastfeeding is 1 of the most important human behaviours for the survival, growth, development and health of infants and young children. Early initiation (within the first hour after birth) and exclusive breastfeeding during the first month is associated with a reduced risk of neonatal morbidity and mortality (Khan et al. 2014). Breastfeeding also offers protection against many conditions, including sudden infant death syndrome, diarrhoea, respiratory infections, middle ear infections and the development of diabetes in later life (Annamalay et al. 2012; Horta et al. 2015).

Key findings

All comparisons between Indigenous and non-Indigenous infants are for ages 0–2 years due to the scope of the ABS National Health Survey 2014–15.

**Children aged 0–3 years:** In New South Wales in 2014–15, 77% of Indigenous children aged 0–3 had been or were currently breastfed. The proportion of Indigenous children who were never breastfed (or for whom breastfeeding status was unknown) was 20%.

Nationally, 80% of Indigenous children aged 0–3 were reported to have been or were currently breastfed, and 20% had never been breastfed, or their breastfeeding status was unknown (Table 2.20.2, Figure 2.20.1).

**Children aged 0–2 years:** In New South Wales in 2014–15, 79% of Indigenous children aged 0–2 were reported to have been breastfed, compared with 85% of non-Indigenous children.

Nationally, a smaller proportion of Indigenous than non-Indigenous children were reported to have been breastfed, the proportions were 82% and 86%, respectively (Table 2.20.6).

**Time breastfed (children aged 0–2 years):** In New South Wales in 2014–15, of Indigenous children who had been breastfed, the most common duration of feeding was 1 month to less than 6 months (27%). The proportion was the same for non-Indigenous children (27%).

Nationally, the most common duration of feeding was 1 month to less than 6 months (24%), the proportion was similar for non-Indigenous children (26%) (Table 2.20.6, Figure 2.20.2).

**Remoteness (children aged 0–2 years):** Nationally, in 2014–15, the proportion of Indigenous children aged 0–2 who were reported to be currently or previously breastfed was highest in Very remote areas (91%) and lowest in Major cities (73%). For non-Indigenous children, the highest proportion was in Outer Regional areas (91%), and the lowest was in Inner Regional areas (80%) (Table 2.20.5).

**Trend over time (children aged 0–3 years):** Nationally between 2004–05 and 2014–15, the rate for breastfeeding of Indigenous infants varied, and no clear trend was discernable. Higher rates of breastfeeding were consistently reported in Remote areas (85% in 2004–05 to 87% in 2014–15) than in Non-remote areas (79% in 2004–05 and 2014–15) (Table 2.20.4, Figure 2.20.3).

2.21 Health behaviours during pregnancy

Why it is important

This measure reports on the use of tobacco, alcohol, illicit substances and other health-related behaviours during pregnancy. Many lifestyle factors contribute to, and can have adverse effects on, the health and wellbeing of a woman and her baby during pregnancy and birth, as well as for children later in life (AHMAC 2017). Smoking tobacco, drinking alcohol and using illicit drugs while pregnant increases the risk of complications and poor perinatal outcomes (England et al. 2004; Hodyl et al. 2014; Laws et al. 2005; Pringle et al. 2015; Wills & Coory 2008). Nutrition before and during pregnancy is critical to fetal development (McDermott et al. 2009; Wen et al. 2010). Drinking alcohol while pregnant has been shown to result in potentially lifelong physical, mental, behavioural and learning issues, collectively referred to as fetal alcohol spectrum disorders (France et al. 2010; Mutch et al. 2015; Srikartika & O’Leary 2015).

Key findings

**Smoking:** In New South Wales in 2014, 45% of Indigenous women who gave birth in 2014 reported that they smoked during pregnancy. The age-standardised rate for Indigenous women was 4 times the rate for non-Indigenous women (45% compared with 11%).

Nationally, the age-standardised rates for women who gave birth in 2014, and reported that they smoked during pregnancy, were 46% for Indigenous women, and 13% for non-Indigenous women (Table 2.21.1; Figure 2.21.1).

**Smoking by remoteness:** Nationally in 2014–15, 38% of mothers of Indigenous children aged 0–3 who lived in Non-remote areas reported that they smoked tobacco during pregnancy, compared with 42% of Indigenous mothers in Remote areas (Table 2.21.7).

**Alcohol consumption:** In New South Wales in 2014–15, 92% of mothers of Indigenous children aged 0–3 reported that they did not consume alcohol during pregnancy.

Nationally, 91% of mothers of Indigenous children aged 0–3 reported that they did not consume alcohol during pregnancy (Table 2.21.6, Figure 2.21.2).

**Illicit drug or substance use:** In New South Wales in 2014–15, 95% of mothers of Indigenous children aged 0–3, who provided information about illicit drug or substance use, reported that they did not use illicit drugs or substances during pregnancy.

Nationally, 96% of mothers of Indigenous children aged 0–3 in 2014–15, reported they did not use illicit drugs or substances during pregnancy (Table 2.21.6, Figure 2.21.3).

**Remoteness:** Nationally, in 2014–15, mothers of Indigenous children aged 0–3 years who lived in Remote areas reported higher proportions of alcohol consumption during their pregnancy than mothers who lived in Non-remote areas, 13% compared with 9%. They also reported higher proportions of tobacco use during pregnancy (42% compared with 38%), and lower proportions of illicit drug use during pregnancy, (2.4% compared with 4.8%) (Table 2.21.7).

Figure 2.21.2: Alcohol consumption by mothers of Indigenous children (aged 0–3) during pregnancy, New South Wales and Australia, 2014–15

Figure 2.21.3: Illicit drug or substance use by mothers of Indigenous children (aged 0–3) during pregnancy, New South Wales and Australia, 2014–15

2.22 Overweight and obesity

Why it is important

This measure reports on the prevalence of overweight and obesity among Indigenous Australians. Overweight and obesity is a global health problem (OECD 2014). Being overweight or obese increases the risk of various health conditions, including coronary heart disease, type 2 diabetes, some cancers, respiratory problems, joint problems, sleep disorders, and social problems. The excess burden of obesity in the Indigenous population is estimated to explain 1 to 3 years (9% to 17%) of the life expectancy gap between Indigenous and non-Indigenous Australians in the Northern Territory (Zhao et al. 2013).

Key findings

Overall: In New South Wales in 2012–13, based on measurements taken at interview, 70% of Indigenous Australians aged 15 and over were overweight (29%) or obese (41%).

Nationally, based on measurements taken at interview, 66% of Indigenous Australians aged 15 and over were overweight (29%) or obese (37%) (ABS 2014b; Figure 2.22.1).

Remoteness: In New South Wales in 2012–13, based on measurements taken at interview, Indigenous Australians aged 18 or over in Remote areas had a higher rate of overweight or obese residents than in Non-remote areas. The age-standardised rate was 77% in Major cities, 76% in Inner regional areas, 76% in Outer regional areas, 79% in Remote areas, and 82% in Very remote areas.

Nationally, based on measurements taken at interview, the age-standardised rate of Indigenous Australians aged 18 or over who were overweight or obese was lower in Remote areas than in Non-remote areas. The proportions were 74% in Major cities, 76% in Inner regional areas, 72% in Outer regional areas, 72% in Remote areas, and 65% in Very remote areas (Table 2.22.3, Figure 2.22.2).

Selected socioeconomic characteristics: Nationally in 2012–13, based on measured data, 40% of Indigenous Australians aged 15 and over who were living in the most advantaged areas (SEIFA fifth quintile) were obese. This was higher than the rate for those living in the most disadvantaged areas (SEIFA first quintile) (37%). The rate of obesity was higher for people who were employed than those who were unemployed (38% compared with 33%). The rate was higher for those with a non-school qualification than for those without (42% compared with 34%) (Table 2.22.1, Figure 2.22.3).

Physical activity: Nationally in 2012–13, of Indigenous Australians aged 18 and over who were obese, a higher proportion reported that they did not meet the physical activity guidelines than those who were not obese (36% compared with 64%) (Table 2.22.2).

Tier 3—Health system performance
3.01 Antenatal care

Why it is important

This measure reports the total number of antenatal visits, duration of pregnancy at first antenatal visit and types of antenatal services used. Antenatal care is especially important for Indigenous women because they are at higher risk of giving birth to pre-term and low birthweight babies and have greater exposure to other risk factors and complications such as anaemia, poor nutritional status, chronic illness, hypertension, diabetes, genital and urinary tract infections, smoking and high levels of psychosocial stressors (AHMAC 2017; de Costa & Wenitong 2009). The World Health Organization recommends receiving antenatal care at least 4 times during pregnancy. The Australian Antenatal Guidelines (AHMAC 2012) recommend that the first antenatal visit occur within the first 10 weeks of pregnancy and that first-time mothers with an uncomplicated pregnancy attend 10 visits (7 visits for subsequent uncomplicated pregnancies).

Key findings

Overall: In New South Wales in 2014, an age-standardised rate of 100% of Indigenous mothers accessed antenatal care services at least once during their pregnancy. The rate was the same for non-Indigenous mothers.

Nationally, an age-standardised rate of 99% of Indigenous mothers accessed antenatal care services at least once during their pregnancy. The age-standardised proportions were similar for Indigenous and non-Indigenous mothers (98.8% and 99.9%, respectively) (Table 3.01.20, Figure 3.01.1).

Number of antenatal visits: In New South Wales in 2014, 89% of Indigenous mothers had 5 or more antenatal visits during pregnancy. The age-standardised rate for Indigenous mothers was 0.9 times the rate for non-Indigenous mothers (90% compared with 96%) (Table 3.01.1).

Nationally, 86% of Indigenous mothers attended 5 or more antenatal visits during pregnancy. The age-standardised rate for Indigenous mothers was 0.9 times the rate for non-Indigenous mothers (86% compared with 95%) (Table 3.01.1).

First antenatal visit: In New South Wales in 2014, 55% of Indigenous mothers had their first antenatal visit in the first trimester of pregnancy. The age-standardised rate for Indigenous mothers who had their first antenatal visit in the first trimester was 0.9 times the rate for non-Indigenous mothers (55% compared with 58%).

Nationally, 54% of Indigenous mothers had their first antenatal visit in the first trimester of pregnancy. The age-standardised rate for Indigenous mothers who had their first antenatal visit in the first trimester was 0.9 times the rate for non-Indigenous mothers (53% compared with 60%) (Table 3.01.10, Figure 3.01.2).

Regular care: In New South Wales in 2014–15, 95% of mothers of Indigenous children aged 0–3 reported they had regular pregnancy check-ups, and 51% had sought advice or information about pregnancy or childbirth.

Nationally, in 2014–15, 94% of mothers of Indigenous children reported they had regular pregnancy check-ups, and 51% had sought advice or information about pregnancy or childbirth (Table 3.01.18, Figure 3.01.3).

3.02 Immunisation

Why it is important

This measure reports on vaccination coverage rates for children aged 1, 2 and 5 years. Vaccination is highly effective in reducing morbidity and mortality caused by vaccine-preventable diseases. Vaccinations have been effective in reducing the disease disparities between Indigenous and non-Indigenous Australians (Menzies & Singleton 2009).

Key findings

Overall: In New South Wales at 31 December 2015, 93% of Indigenous and non-Indigenous children aged 1 were fully vaccinated (Table 3.02.2, Figure 3.02.1). At age 2, 89% of Indigenous children were fully vaccinated, compared with 90% of other children (Table 3.02.3, Figure 3.02.2). By age 5, the rate for Indigenous Australians (95%) was higher than for other Australian children (93%) (Table 3.02.4, Figure 3.02.3).

Nationally, 90% of Indigenous children aged 1 were fully vaccinated, compared with 93% for other Australian children (Table 3.02.2, Figure 3.02.1). At age 2, 87% of Indigenous children were fully vaccinated, compared with 90% for other children (Table 3.02.3, Figure 3.02.2). By age 5, 95% of Indigenous children were fully vaccinated, compared with 93% for other Australian children (Table 3.02.4, Figure 3.02.3).

At age 1: In New South Wales at 31 December 2015, for Indigenous children aged 1, the vaccination rates for hepatitis B, diphtheria, tetanus, pertussis, polio, Haemophilus influenzae B, and pneumococcal were all 93%. The proportions for other children were 94%, except pneumococcal, which was 93%.

Nationally, the vaccination rates for Indigenous children were lower than for other children (90% for all compared with 94% for all) (Table 3.02.2, Figure 3.02.1).

At age 2: In New South Wales at 31 December 2015, for children aged 2, the vaccination rates for hepatitis B, diphtheria, tetanus, pertussis, polio, and Haemophilus influenzae B were slightly higher for Indigenous children (96% for all) than for other children (95% for all vaccinations, except Haemophilus influenzae B, which was 94%). The rates for measles, mumps, rubella (91%), and varicella (90%) were slightly lower for Indigenous children than for other children (92% for both).

Nationally, the rates for hepatitis B and polio vaccine at age 2 were higher for Indigenous children than for other children (96% compared with 95%). For diphtheria, tetanus, pertussis, the rate for both Indigenous and other children was 96%, and for Haemophilus influenzae B, the rate was 95% for both. The rates for measles, mumps, rubella and varicella were lower for Indigenous children (89% for both) than for other children (92% for both) (Table 3.02.3, Figure 3.02.2).

At age 5: In New South Wales at 31 December 2015, for children aged 5, the vaccination rates for diphtheria, tetanus, pertussis, polio, and measles, mumps, rubella for Indigenous children were all 96%, which was higher than for other children (94% for all vaccinations).

Nationally, the vaccination rates for Indigenous children for diphtheria, tetanus, pertussis, and polio were both 95%, which was higher than the rates for other children (94% for both). The rate for measles, mumps, rubella was higher for Indigenous children than for other children (96% compared with 94%) (Table 3.02.4, Figure 3.02.3).

3.03 Health promotion

Why it is important

This measure reports on interventions provided by clinicians and health promotion initiatives funded by governments and provided by a range of health professionals. Indigenous Australians experience higher levels of morbidity and mortality from potentially avoidable conditions than other Australians (AHMAC 2017). Health promotion is the process of enabling people to increase control over their health and its determinants, and improve their health as a result (WHO 2005). Health promotion includes: public policy interventions (for example, packaging of cigarettes, seat belt laws); information to support healthy lifestyles (for example, smoking, alcohol and drug use, physical activity and diet); social marketing (for example, sunscreen use); and mass media campaigns (for example, drink-driving, road safety) (AHMAC 2015).

Key findings

Overall: In New South Wales in 2012–13, 86% of Indigenous Australians aged 15 and over reported they had consulted a doctor in the previous 12 months. Of those who had consulted a doctor, 49% reported they had discussed lifestyle issues with a GP or health professional. Nationally, 83% of Indigenous Australians aged 15 and over reported they had consulted a doctor in the previous 12 months. Of those who had consulted a doctor, 46% reported they had discussed lifestyle issues with a GP or health professional (Table 3.03.4, Figure 3.03.1).

Lifestyle information: In New South Wales in 2012–13, Indigenous Australians aged 15 and over reported that the most common lifestyle issues discussed with a GP or health professional were reaching a healthy weight (55%), eating healthy food or improving their diet (47%), reducing or quitting smoking (44%), and increasing physical activity (36%). Nationally, Indigenous Australians aged 15 and over reported that the most common lifestyle issues discussed with a GP or health professional were reaching a healthy weight (50%), eating healthy food or improving their diet (44%), reducing or quitting smoking (43%), and increasing physical activity (30%) (Table 3.03.4, Figure 3.03.2).

Programs and activities: In New South Wales and the Australian Capital Territory combined, between 1 June 2014 and 31 May 2015, when data were combined from all Indigenous-specific health-care services, the most common type of health promotion activities and programs provided by Aboriginal and Torres Strait Islander primary health-care organisations were physical activity or healthy weight programs and activities (86%), men’s groups (61%), chronic disease client support groups (61%), and living skills groups, such as cooking or nutrition groups (59%). Nationally, between 1 June 2014 and 31 May 2015, the most common type of health promotion activities and programs provided by Aboriginal and Torres Strait Islander primary health-care organisations were physical activity or healthy weight programs and activities (73%), men’s groups (64%), women’s groups (63%), and living skills groups, such as cooking or nutrition groups (61%) (Table 3.03.10, Figure 3.03.3).

3.04 Early detection and early treatment

Why it is important

This measure reports on the early detection and early treatment of disease. Early detection is the discovery of a disease or condition at an early stage, usually before symptoms occur. This means the disease can be treated much earlier, which results in better health outcomes for patients. Medicare Benefits Schedule (MBS) health assessment items for Indigenous Australians encourage early detection, diagnosis and intervention for common and treatable conditions that cause morbidity and early mortality. Screening programs are designed to detect cancer early (breast and bowel) or prevent its occurrence in the first place by detecting pre-cancerous changes (bowel and cervical) (AHMAC 2017; AIHW 2016d).

Key findings

Medicare health assessments: In New South Wales in 2015–16, the rate of Indigenous-specific health checks claimed (MBS item 715) was 247 per 1,000. The rate in all age groups was lower for Indigenous Australians in New South Wales than the equivalent national rates. By age group, the rates were 236 per 1,000 for those aged 0–14, 231 per 1,000 for those aged 15–54, and 362 per 1,000 for those aged 55 and over.

Nationally in 2015–16, the rate of Indigenous-specific health checks claimed (MBS item 715) was 267 per 1,000. By age group, the rates were 256 per 1,000 for those aged 0–14, 252 per 1,000 for those aged 15–54, and 383 per 1,000 for those aged 55 and over (Table 3.04.1, Figure 3.04.1).

Breast cancer screening: In New South Wales in 2013–2014, the age-standardised rate for Indigenous women aged 50–69 who had been screened for breast cancer through the BreastScreen Australia program was 34%, compared with 51% for non-Indigenous women.

Nationally, the age-standardised rate for Indigenous women aged 50–69 who had been screened for breast cancer was 37%, compared with 54% for non-Indigenous women (Table 3.04.9, Figure 3.04.2).

Pap smear test: In New South Wales in 2012–13, 67% of Indigenous women aged 20–69 reported they had regular pap smear tests.

Nationally, 70% of Indigenous women aged 20–69 reported they had regular pap smear tests (Table 3.04.13).

Bowel cancer screening: In New South Wales in 2012–13, 20% of Indigenous males and 17% of Indigenous females aged 50–74 reported they had participated in bowel cancer screening tests.

Nationally, 18% of Indigenous males and 11% of Indigenous females aged 50–74 reported they had participated in bowel cancer screening tests (Table 3.04.17).

Trend over time: In New South Wales the rate of Indigenous-specific health checks claimed (MBS item 715) for all age groups rose from 30 per 1,000 in 2006–07 to 247 per 1,000 in 2015–16 (Table 3.04.3). Increases were evident for all age groups, with the largest being for those aged 55 and over (tables 3.04.5, 3.04.6, 3.04.7, Figure 3.04.3).

Nationally, the rate for all age groups rose from 37 per 1,000 in 2006–07 to 267 per 1,000 in 2015–16 (Table 3.04.3). Increases were evident in all age groups, with the largest being for those aged 55 and over (tables 3.04.5, 3.04.6, 3.04.7, Figure 3.04.3).

Australians, by age group (years), New South Wales and Australia, 2006–07 to 2015–16

Tables referenced, and data sources and quality: see <www.aihw.gov.au/
3.05 Chronic disease management

Why it is important

This measure reports on the management of chronic diseases. Chronic diseases are the leading causes of illness, disability and death among Indigenous Australians and are estimated to be responsible for 70% of the health gap between Indigenous and non-Indigenous Australians (AIHW 2016b). Effective management of chronic diseases is key in meeting the target of closing the life expectancy gap between Indigenous and non-Indigenous Australians within a generation. Effective management of chronic diseases can delay the progression of the disease, improve quality of life, increase life expectancy and decrease the need for high cost interventions leading to net savings (Thomas et al. 2014; Zhao et al. 2014).

Key findings

Blood tests and foot checks: In New South Wales in 2012–13, of all Indigenous Australians with current and long-term diabetes or high sugar levels, 71% reported having undergone glycated haemoglobin (A1c) (HbA1C) testing in the previous 12 months, compared with 78% for non-Indigenous Australians. Blood glucose levels were checked for 96% of Indigenous Australians, compared with 99.7% for non-Indigenous Australians. Feet were checked for 69% of Indigenous Australians, compared with 75% for non-Indigenous Australians (Table 3.05.13, Figure 3.05.1).

Nationally, of Indigenous Australians with current and long-term diabetes or high sugar levels, 69% reported having undergone HbA1C testing in the previous 12 months, compared with 72% for non-Indigenous Australians. Blood glucose levels were checked for 95% of Indigenous Australians, compared with 97% for non-Indigenous Australians. Feet were checked for 68% of Indigenous Australians, compared with 74% for non-Indigenous Australians (Table 3.05.13, Figure 3.05.1).

Actions taken: In New South Wales in 2012–13, Indigenous Australians reported that actions they had taken to manage current and long-term diabetes or high sugar levels included: a lifestyle action, such as diet, weight loss, or exercise (85%); taking medicine or tablets (67%); and using insulin (34%).

Nationally, Indigenous Australians reported that actions they had taken to manage current and long-term diabetes or high sugar levels included: a lifestyle action such as diet, weight loss, or exercise (80%); taking medicine or tablets (64%); and using insulin (30%) (Table 3.05.13, Figure 3.05.2).

Trend over time: In New South Wales and the Australian Capital Territory combined, the proportion of Indigenous clients of Indigenous-specific primary health services (ISPHS) with type 2 diabetes who had a GP Management Plan (GPMP) in the previous 2 years rose from 46% in 2012 and to 53% in 2014. A similar pattern was seen for ISPHS clients with a team care arrangement (TCA), with a rise from 44% in 2012 to 52% in 2014.

Nationally, the proportion of all ISPHS clients with type 2 diabetes who had a GPMP in the previous 2 years rose from 41% in 2012 to 51% in 2015. The proportion of ISPHS clients with a team care arrangement (TCA) also rose, from 36% in 2012 to 48% in 2015 (Table 3.18.1, Figure 3.05.3).

3.06 Access to hospital procedures

Why it is important

This measure reports on the key hospital procedure differences between Indigenous and non-Indigenous Australians for hospitalisation with the same principal diagnosis. Studies have shown that, although Indigenous Australians are more likely to be hospitalised than non-Indigenous Australians, they are less likely to receive a medical or surgical procedure while in hospital. The disparities are not explained by diagnosis, age, sex or place of residence (ABS & AIHW 2008; Cunningham 2002). Research has shown that the most significant factors were: whether the hospital was public or private hospital, the number of principal and additional diagnoses, state/territory of usual residence, indigenous status, age group, remoteness of usual residence, and sex (AHMAC 2017).

Key findings

Overall: In New South Wales between July 2013 and June 2015, the age-standardised rate of hospitalisations where a procedure was recorded was 63% for Indigenous Australians, compared with 80% for non-Indigenous Australians, a difference of 17 percentage points. Nationally, the age-standardised rate of hospitalisations where a procedure was recorded was 62% for Indigenous Australians, compared with 81% for non-Indigenous Australians, a difference of 19 percentage points (Table 3.06.1, Figure 3.06.1).

Procedures by age: Nationally, the proportion of hospitalisations for Indigenous Australians where a procedure was reported increased with age, from 47% for those aged 0–4, to 70% for those aged 65 and over. For non-Indigenous Australians, proportions were higher for every age group, for example, 54% for those aged 0–4, and 86% for those aged 65 and over (Table 3.06.4).

Main diagnosis: In New South Wales between July 2013 and June 2015, the age-standardised rate for hospitalisation where a procedure was recorded was highest for diseases of the eye for both Indigenous Australians (96%) and non-Indigenous Australians (98%). This was followed by hospitalisation for cancers (neoplasms) (90% for Indigenous Australians, and 96% for non-Indigenous Australians), and diseases of the blood (88% for Indigenous Australians, and 92% for non-Indigenous Australians).

Nationally between July 2013 and June 2015, the age-standardised rate for hospitalisation where a procedure was recorded was highest for diseases of the eye for both Indigenous Australians (93%) and non-Indigenous Australians (99%). This was followed by hospitalisations for cancers (neoplasms) (91% for Indigenous Australians, and 96% for non-Indigenous Australians), and diseases of the blood (89% for Indigenous Australians, and 94% for non-Indigenous Australians) (Table 3.06.2 NSW, Figure 3.06.2).

Trend over time: Nationally, the age-standardised rate of hospitalisation for Indigenous Australians where a procedure was recorded rose by 13%, from 53% in 2004–05 to 63% in 2014–15. The gap between Indigenous and non-Indigenous Australians narrowed by 29%, from 26% in 2004–05 to 17% in 2014–15 (Table 3.06.11).
Figure 3.06.1: Age-standardised proportion of hospitalisations with a procedure recorded, by Indigenous status, New South Wales and Australia, July 2013 to June 2015

Figure 3.06.2: Age-standardised rate of hospitalisations with a procedure recorded, by diagnosis and Indigenous status, New South Wales and Australia, July 2013 to June 2015

3.07 Selected potentially preventable hospital admissions

Why it is important
This measure reports on the number of hospitalisations for potentially preventable conditions. Systematic differences in hospitalisation rates for Indigenous and non-Indigenous Australians could indicate gaps in the provision of population health interventions (such as vaccination), primary care services (for example, early interventions to detect and treat chronic disease) and continuing care support (for example, care planning for people with chronic illnesses, such as congestive heart failure) (AHMAC 2017).

Key findings

Overall: In New South Wales between July 2013 and June 2015, the age-standardised rate for potentially preventable hospitalisations for Indigenous Australians was 2.5 times the rate for non-Indigenous Australians (54 per 1,000 compared with 22 per 1,000). The rate for Indigenous males was 52 per 1,000, this was lower than the rate for Indigenous females (56 per 1,000). For non-Indigenous Australians the rates for males and females were similar (22.3 and 21.6 per 1,000) (Table 3.07.2, Figure 3.07.1).

Nationally, the age-standardised rate for potentially preventable hospitalisations for Indigenous Australians was 3 times the rate for non-Indigenous Australians (69 per 1,000 compared with 23 per 1,000). The rate for Indigenous males (66 per 1,000) was lower than the rate for Indigenous females (73 per 1,000). For non-Indigenous Australians the rates for males (24 per 1,000) and females (23 per 1,000) were similar (Table 3.07.1, Figure 3.07.1).

Reason for hospitalisation: In New South Wales between July 2013 and June 2015, the age-standardised rates for potentially preventable hospitalisations for Indigenous Australians were: 30 per 1,000 for chronic conditions; 21 per 1,000 for acute conditions; and 3 per 1,000 for vaccine-preventable conditions. Age-standardised rates for potentially preventable hospitalisations for non-Indigenous Australians were lower, at 10 per 1,000 for chronic conditions, 11 per 1,000 for acute conditions, and 1 per 1,000 for vaccine-preventable conditions.

Nationally, the age-standardised rates for potentially preventable hospitalisations for Indigenous Australians were: 34 per 1,000 for chronic conditions; 28 per 1,000 for acute conditions; and 8 per 1,000 for vaccine-preventable conditions. For non-Indigenous Australians, the rates were 11 per 1,000 for both chronic and acute conditions, and 1 per 1,000 for vaccine-preventable conditions (Table 3.07.4 NSW, Figure 3.07.2).

Age: In New South Wales between July 2013 and June 2015, the rate of potentially preventable hospitalisations was higher for Indigenous than for non-Indigenous Australians across all age groups. The rate was highest for those aged 65 and over for both Indigenous Australians (156 per 1,000), and non-Indigenous Australians (75 per 1,000).

Nationally, the rate for was higher for Indigenous than non-Indigenous Australians across all age groups. The rate was highest for those aged 65 and over for both Indigenous Australians (171 per 1,000), and non-Indigenous Australians (78 per 1,000) (Table 3.07.1 NSW, Figure 3.07.3).

Figure 3.07.2: Age-standardised hospitalisation rate for potentially preventable hospitalisations, by condition and Indigenous status, New South Wales and Australia, July 2013 to June 2015

Figure 3.07.3: Hospitalisation rate for potentially preventable hospitalisations, by age group (years) and Indigenous status, New South Wales and Australia, July 2013 to June 2015

### 3.08 Cultural competency

#### Why it is important

This measure reports on aspects of cultural competency, including discrimination and barriers to accessing services for Indigenous Australians. Improving the cultural competency of health-care services can increase Indigenous Australians’ access to health care, increase the effectiveness of care that is received, and improve the disparities in health outcomes (Freeman et al. 2014). Cultural competency can be measured directly (self-reporting on patient experience) or indirectly (for example, discharge against medical advice—see Measure 3.09—and employment of Indigenous health workers) (AHMAC 2017). However, there is limited data available on the cultural competence of health services (Paradies et al. 2014) or on effectiveness of interventions to address cultural competency in health care for Indigenous people (Clifford et al. 2015; Truong et al. 2014).

#### Key findings

**Overall:** In New South Wales in 2012–13, 35% of Indigenous Australians aged 2 and over were reported to have not seen a health provider when it was necessary. The dentist was the most common service not accessed when needed (25%), with cost being the most common reason (45%). For Indigenous Australians of all ages, other services that were not accessed when needed included doctors (16%), other health professionals (11%), and hospitals (6%). For those aged 18 and over, 12% didn’t access counsellors.

Nationally, 30% of Indigenous Australians aged 2 and over were reported to have not seen a health provider when it was necessary. The dentist was the most common service not accessed when needed (20%), with cost being the most common reason (43%). For Indigenous Australians of all ages, other services not accessed when needed included doctors (14%), other health professionals (9%), and hospitals (6%). For those aged 18 and over, 9% didn’t access counsellors (Table 3.08.4, Figure 3.08.1).

**Barriers:** In New South Wales in 2012–13, 38% of all Indigenous Australians reported that they didn’t access a health provider due to logistical reasons (including waiting time was too long or not available at the time it was required; transport or distance; and service was not available in the area). Further, 31% of Indigenous Australians didn’t access a health service for reasons relating to the cultural appropriateness of the service (discrimination or language problems; dislike of the service or professional; was embarrassed or afraid; felt the service would be inadequate; or didn’t trust the service).

Nationally, 40% of all Indigenous Australians reported that they didn’t access a health service for logistical reasons, and 32% for reasons relating to the cultural appropriateness of the service (Table 3.08.4, Figure 3.08.2).

**Patient experience:** In New South Wales in 2012–13 in non-remote areas, Indigenous Australians aged 15 and over responded with always/usually when asked how often doctors: spent enough time with the patient (84%); explained things in a way that could be understood (85%); listened (88%); and showed respect for what was said (88%).

Nationally in non-remote areas, Indigenous Australians aged 15 and over responded with always/usually to how often doctors: spent enough time with the patient (85%); explained things in a way that could be understood (87%); listened (89%); and showed respect for what was said (89%) (Table 3.08.7, Figure 3.08.3).
Data for dentist are for those aged 2 and over. Data for counsellor are for those aged 18 and over.

Figure 3.08.2: Proportion of Indigenous Australians who didn’t access a health provider when needed who reported this was due to logistical reasons or cultural appropriateness of service, by health provider type, New South Wales and Australia, 2012–13

Figure 3.08.3: Patient experience, Indigenous Australians (aged 15 and over), by type of doctor behaviour, New South Wales and Australia (Non-remote areas), 2012–13

3.09 Discharge against medical advice

Why it is important

This measure reports on the rate at which Indigenous Australians leave hospital against medical advice or are discharged at their own risk. People who take their own leave from hospital are more likely to present again at emergency departments, and have higher death rates. The reasons for which Indigenous Australians take their own leave from hospital include: institutionalised racism, a lack of cultural safety, a distrust of the health system, family and social obligations, isolation and loneliness, a lack of understanding of the treatment they were receiving and feeling that the treatment had finished, and communication and language barriers between staff and patient (AHMAC 2017; Shaw 2016).

Key findings

Overall: In New South Wales between July 2013 and June 2015, the proportion of hospitalisations of Indigenous Australians where patients left against medical advice or were discharged at their own risk was 3.1%. The age-standardised rate where Indigenous patients left against medical advice, or were discharged at their own risk, was at 3.9 times the rate of non-Indigenous patients (2.5% compared with 0.6%).

Nationally, the proportion of hospitalisations of Indigenous Australians where patients left against medical advice or were discharged at their own risk was 4.3%. The age-standardised rate where Indigenous patients left against medical advice, or were discharged at their own risk, was 7.1 times the for non-Indigenous patients (3.4% compared with 0.5%) (Table 3.09.3, Figure 3.09.1).

Age groups: In New South Wales between July 2013 and June 2015, higher proportions of Indigenous Australians than non-Indigenous Australians in all age groups left hospital against medical advice or were discharged at their own risk. Indigenous Australians aged 35–44 had the highest proportion of hospitalisations where patients left hospital against medical advice or were discharged at their own risk (5.8%). For non-Indigenous Australians the highest proportion was for those aged 15–24 (1.4%).

Nationally, higher proportions of Indigenous Australians than non-Indigenous Australians in all age groups left hospital against medical advice or were discharged at their own risk. Indigenous Australians aged 35–44 had the highest proportion of hospitalisations where patients left hospital against medical advice or were discharged at their own risk (8.1%). For non-Indigenous Australians, the highest proportion was for those aged 15–24 (1.0%) (Table 3.09.1 NSW, Figure 3.09.2).

Principal diagnosis: In New South Wales between July 2013 and June 2015, the highest age-standardised rate of hospitalisations where Indigenous patients left hospital or were discharged at their own risk was for endocrine, nutritional and metabolic disorders (for example, type 2 diabetes) (4.1%), diseases of the skin (for example, sunburn), and injury and poisoning (for example, fracture) (both 4.0%).

Nationally, the highest age-standardised rate of hospitalisations where Indigenous patients left hospital or were discharged at their own risk was for endocrine, nutritional and metabolic disorders (6.4%), and diseases of the skin (5.6%) (Table 3.09.7 NSW, Figure 3.09.3).

### 3.10 Access to mental health services

#### Why it is important

This measure reports on access to mental health-care services such as hospitals, community mental health-care, doctors and Aboriginal and Torres Strait Islander primary health-care services. Indigenous Australians experience higher rates of mental health issues than other Australians, with deaths from suicide twice as high, hospitalisation rates for intentional self-harm 2.7 times as high, and rates of high/very high psychological distress 2.6 times as high as for other Australians (AHMAC 2017). Mental health care may be provided by specialised mental health-care services (for example, private psychiatrists, and specialised hospital, residential or community services), or by general health-care services that supply mental health-related care (for example, GPs and Indigenous primary health-care organisations) (AHMAC 2017).

#### Key findings

**Community service contacts:** In New South Wales in 2014–15, community mental health services reported 362,066 service contacts for Indigenous clients. The age-standardised rate for Indigenous clients was 5.4 times the rate for non-Indigenous clients (1,847 per 1,000 compared with 340 per 1,000).

Nationally, the age-standardised rate for community mental health services contacts for Indigenous clients was 1,155 per 1,000, this was 3.5 times the rate for non-Indigenous clients (326 per 1,000) (Table 3.10.4, Figure 3.10.1).

**Residential mental health-care episodes:** In New South Wales in 2014–15, there were 40 residential mental health-care episodes reported for Indigenous clients. The age-standardised rate of residential mental health-care episodes for Indigenous Australians was 5.8 times the rate for non-Indigenous Australians (2.5 per 10,000 compared with 0.4 per 10,000).

Nationally, the age-standardised rate for residential mental health-care episodes for Indigenous Australians was 6.2 per 10,000. For non-Indigenous Australians the rate was 3.2 per 10,000 (Table 3.10.5, Figure 3.10.2).

**Psychiatric hospital beds:** In New South Wales in 2013–14, the rate of available psychiatric beds in public psychiatric hospitals was 12 per 100,000, higher than the national rate of 7.6 per 100,000 (Table 3.10.10).

**Trend over time:** In New South Wales, the age-standardised hospitalisation rate for mental health-related conditions for Indigenous Australians rose by 18%, from 25 per 1,000 in 2004–05 to 30 per 1,000 in 2014–15. The age-standardised rate for non-Indigenous Australians rose from 14 per 1,000 in 2004–05 to 18 per 1,000 in 2014–15.

For NSW, Vic, Qld, WA, SA and NT combined, the age-standardised hospitalisation rate for mental health-related conditions for Indigenous Australians rose by 46% from 21 per 1,000 in 2004–05 to 29 per 1,000 in 2014–15. The rate for non-Indigenous Australians rose by 6% from 15 per 1,000 in 2004–05 to 16 per 1,000 in 2014–15 (Table 3.10.9 NSW, Figure 3.10.3).

3.11 Access to alcohol and drug services

Why it is important

This measure reports on access to alcohol and drug services. Alcohol and substance misuse causes a wide range of harms including: mental health issues, chronic disease (for example, liver disease), bloodborne virus spread, injuries from motor vehicle accidents and assaults, incarceration, and social disruptions including family breakdown. Alcohol and substance-use services provide various interventions and support that seek to tackle harmful alcohol and other drug use, and restore the physical, social and emotional wellbeing of clients and families (NIDAC 2014).

Key findings

Substance use: In New South Wales in 2014–15, 31% of Indigenous Australians aged 15 and over reported using substances in the previous 12 months. Nationally, an estimated 31% of Indigenous Australians reported using substances in the previous 12 months (Table 2.17.3, Figure 3.11.1).

Pharmacotherapy: In New South Wales on a ‘snapshot’ day in 2016, 2,463 Indigenous Australians were receiving pharmacotherapy (including methadone, buprenorphine, and buprenorphine/naloxone), a rise from 1,469 in 2006. The number of non-Indigenous Australians receiving pharmacotherapy also rose, from 11,898 in 2006 to 15,543 in 2016. In NSW, Qld, SA and the ACT combined, 3,129 Indigenous Australians were receiving pharmacotherapy in 2015, an increase from 1,662 in 2006. There was also an increase for non-Indigenous Australians receiving pharmacotherapy, from 16,354 in 2006 to 24,190 in 2015 (Table 3.11.4). Note that for 2006, Indigenous data was not available for South Australia and for 2016, data had not yet been published for the ACT.

Primary health-care services: Between June 2014 and May 2015, in New South Wales and the Australian Capital Territory combined, 36% of Aboriginal and Torres Strait Islander primary health-care organisations provided alcohol use treatment or prevention groups, and 57% provided tobacco use treatment or prevention groups. Nationally, 40% of Aboriginal and Torres Strait Islander primary health-care organisations provided alcohol use treatment or prevention groups, and 56% provided tobacco use treatment or prevention groups (Table 3.03.10, Figure 3.11.2).

Hospitalisations: In New South Wales between July 2013 and June 2015, the age-standardised rate of Indigenous Australians who were hospitalised for reasons relating to alcohol use was 2.5 times the rate for non-Indigenous Australians (6.6 compared with 2.6 per 1,000). The rate was higher for Indigenous males (9.2 per 1,000) than for Indigenous females (4.2 per 1,000). The rate was also higher for non-Indigenous males (3.1 per 1,000) than for non-Indigenous females (2.1 per 1,000).

Nationally, the age-standardised rate for Indigenous Australians who were hospitalised for reasons relating to alcohol use was 3.9 times the rate for non-Indigenous Australians (9.0 compared with 2.3 per 1,000). The rate was higher for Indigenous males (11 per 1,000) than for Indigenous females (7.2 per 1,000). It was also higher for non-Indigenous males (2.6 per 1,000) than for non-Indigenous females (2.0 per 1,000) (Table 2.16.15, Figure 3.11.3).

3.12 Aboriginal and Torres Strait Islander people in the health workforce

Why it is important

This measure reports on Indigenous Australians employed in the health workforce. Indigenous Australians are significantly under-represented in the health workforce, which potentially contributes to reduced access to health services for the broader Indigenous Australian population. The Indigenous workforce is integral to ensuring that the health system can address the needs of Indigenous Australians. Indigenous health professionals can align their unique technical and sociocultural skills to improve patient care, improve access to services and ensure culturally appropriate care in the services that they and their non-Indigenous colleagues deliver (Anderson et al. 2009; West et al. 2010).

Key findings

Overall: In New South Wales in 2014 and 2015, 1,600 Indigenous Australians were employed in registered health professions, compared with 149,212 non-Indigenous Australians. The rate of Indigenous Australians employed in registered health professions was 710 per 100,000, compared with 2,018 per 100,000 for non-Indigenous Australians. Nationally, of those who identified as being Indigenous, 4,471 Indigenous Australians were employed in registered health professions, compared with 502,667 non-Indigenous Australians. The rate for Indigenous Australians was 613 per 100,000, compared with 2,181 per 100,000 non-Indigenous Australians (Table 3.12.4, Figure 3.12.1).

Medical practitioners: In New South Wales in 2015, 148 Indigenous Australians were employed as medical practitioners, representing 0.6% of employed medical practitioners in the state (Table 3.12.6). The rates for Indigenous and non-Indigenous Australians employed as medical practitioners were 66 and 355 per 100,000, respectively—a difference of 289 per 100,000 (Table 3.12.4, Figure 3.12.2).

Nationally, 409 Indigenous Australians were employed as medical practitioners, representing 0.5% of employed medical practitioners in Australia (Table 3.12.6). The rates for Indigenous and non-Indigenous Australians employed as medical practitioners were 56 and 353 per 100,000, respectively—a difference of 297 per 100,000 (Table 3.12.4, Figure 3.12.2).

Nurses and midwives: In New South Wales in 2015, 1,188 Indigenous Australians were employed as nurses and midwives, representing 1.4% of employed nurses and midwives in the state (Table 3.12.9). The rates for Indigenous and non-Indigenous Australians employed as nurses and midwives were 527 and 1,138 per 100,000, respectively—a difference of 610 per 100,000 (Table 3.12.4, Figure 3.12.3).

Nationally, 3,187 Indigenous Australians were employed as nurses and midwives, representing 1.1% of employed nurses and midwives in Australia (Table 3.12.9). The rates for Indigenous and non-Indigenous Australians employed as nurses and midwives were 437 and 1,295 per 100,000, respectively—a difference of 858 per 100,000 (Table 3.12.4, Figure 3.12.3).
Note: Medical practitioners and nurses/midwives data are from 2015; other types of health professions are from 2014.

Figure 3.12.3: Rate of employed nurses and midwives, by Indigenous status, New South Wales and Australia, 2015

3.13 Competent governance

Why it is important

This measure reports on governance in Indigenous-specific and mainstream health services. Governance refers to the evolving processes, relationships, institutions and structures by which a group of people, community or society organise themselves collectively to achieve things that matter to them (Hunt et al. 2008). The way governance functions are done has a direct impact on the wellbeing of individuals and communities (AHMAC 2017).

Key findings

**Indigenous specific primary health-care organisations:** In New South Wales between 1 June 2014 and 31 May 2015, 41 Indigenous primary health-care organisations had a governing committee or board. For 40 of the organisations (98%), the frequency of meetings met the requirement of the constitution, and all had income and expenditure statements presented on at least 2 occasions. For 31 of the organisations (76%), all of the committee or board members were Indigenous Australians, and 31 of the organisations (76%) received training on governing committee or board functions (Table 3.13.3 NSW, Figure 3.13.1).

Nationally, of the 203 Indigenous primary health-care organisations, 163 (80%) reported having a governing committee or board. Of these, 159 (98%) had met the requirement of the constitution for the frequency of meetings, and 159 (98%) had income and expenditure statements presented on at least 2 occasions. Almost three-quarters (120 or 74%) of the members were Indigenous Australians and 128 (79%) received training on governing committee or board functions (Table 3.13.3, Figure 3.13.1).

**Indigenous specific substance-use services:** In New South Wales between 1 June 2014 and 31 May 2015, 15 substance-use services had a governing committee or board. All of them met the requirement of the constitution for the frequency of meetings, and all had income and expenditure statements presented on at least 2 occasions. Almost three-quarters (11 or 73%) of the committees or boards were entirely comprised of Indigenous Australians, and 14 (93%) received training on governing committee or board functions (Table 3.13.4 NSW, Figure 3.13.2).

Nationally, of 67 Indigenous substance-use services, 65 reported have a governing committee or board. Of these, 64 (99%) had met the requirement of the constitution for the frequency of meetings, and all had income and expenditure statements presented on at least 2 occasions. More than half (36 or 55%) of the committees or boards were entirely comprised of Indigenous Australian members and 53 (82%) received training on governing committee or board functions (Table 3.13.4, Figure 3.13.2).

**Mainstream processes participation:** In New South Wales between 1 June 2014 and 31 May 2015, of the 43 Indigenous health services, 35 (81%) had representatives on external boards (for example, hospitals), and 39 (91%) participated in regional health planning processes (Table 3.13.5 NSW, Figure 3.13.3).

Nationally, of the 203 Indigenous health services, 128 (63%) had representatives on external boards (for example, hospitals), 175 (86%) participated in regional health planning processes (Table 3.13.5, Figure 3.13.3).

3.14 Access to services compared with need

Why it is important

This measure reports on the use of various types of health services (for example, primary care, hospital, dental and allied health and post-acute care and palliative care) and potential barriers to accessing these services. Indigenous Australians have significantly poorer health status than non-Indigenous Australians. Inequalities in health care access and use may further exacerbate inequalities in health status (OECD 2009). As a result, access to health care when needed is essential to closing the gap in life expectancy.

Key findings

Use of services: In New South Wales in 2012–13, 43% of Indigenous Australians were reported to have accessed health care in the previous 2 weeks—23% had consulted a doctor or specialist, 5% had visited casualty or outpatient services, and 4% (of those aged over 2) had seen a dentist. In the previous 12 months, 18% had been admitted to hospital.

Nationally, 44% of Indigenous Australians were reported to have accessed health care in the previous 2 weeks—22% had consulted a doctor or specialist, 5% had visited casualty or outpatient services, and 5% (of those aged over 2) had seen a dentist. In the previous 12 months, 18% had been admitted to hospital (Table 3.14.3, Figure 3.14.1).

Services claimed through Medicare: In New South Wales in 2015–16, the rate of services claimed through the MBS for Indigenous Australians was 13,370 per 1,000 (Table 3.14.30). The age-standardised rate of claims was similar for Indigenous and non-Indigenous Australians (16,653 and 16,033 per 1,000, respectively) (Table 3.14.31, Figure 3.14.2).

Nationally, the rate of claimed MBS services for Indigenous Australians was 11,787 per 1,000 (Table 3.14.30). The age-standardised rate of claims was similar for Indigenous Australians (14,622 per 1,000) and for non-Indigenous Australians (15,063 per 1,000) (Table 3.14.31, Figure 3.14.2).

Hospitalisation for palliative care: In New South Wales between July 2013 and June 2015, the age-standardised rate of hospitalisation for palliative care for Indigenous Australians was 2.9 per 1,000, almost twice the rate for non-Indigenous Australians (1.5 per 1,000) The rate for Indigenous males was higher than the rate for Indigenous females (3.0 compared with 2.8 per 1,000). The rate for non Indigenous males was higher than the rate for non-Indigenous females (1.7 compared with 1.3 per 1,000).

Nationally, the age-standardised rate of hospitalisation for palliative care for Indigenous Australians was 2.7 per 1,000. 1.9 times the rate for non-Indigenous Australians (1.5 per 1,000). The rate for Indigenous males was higher than the rate for Indigenous females (3.0 per 1,000 compared with 2.5 per 1,000). The rate for non-Indigenous males was higher than the rate for non-Indigenous females (1.7 per 1,000 compared with 1.3 per 1,000) (Table 3.14.48, Figure 3.14.3).

Elective surgery: In New South Wales between July 2013 and June 2015, 2% of Indigenous elective surgery patients had a waiting time of more than 1 year, compared with 1.7% for non-Indigenous patients.

Nationally (excluding the Australian Capital Territory, as data was not available at the time of reporting), 2.5% of Indigenous elective surgery patients had a waiting time of more than 1 year, compared with 2% for non-Indigenous patients (Table 3.14.51).

Figure 3.14.3: Age-standardised rate of hospitalisation for palliative care, by sex and Indigenous status, New South Wales and Australia, July 2013 to June 2015

3.15 Access to prescription medicines

Why it is important

This measure reports on: expenditure on pharmaceuticals, the Pharmaceutical Benefits Scheme (PBS) and reasons Indigenous Australians might not access prescription medicines. Essential medicines save lives and improve health when they are available, affordable and quality-assured, and properly used. Affordable access to medicines is important for many acute and chronic illnesses. For chronic illnesses, such as diabetes, hypertension, heart disease and renal failure, multiple medications might be required for many years to avoid complications (WHO 2004). It is important to ensure that Indigenous Australians, who experience high rates of acute and chronic illnesses, are able to access appropriate prescription medications when required (AHMAC 2017).

Key findings

Expenditure per person: Nationally in 2013–14, total expenditure (government and non-government) on pharmaceuticals per person for Indigenous Australians was less than the amount spent per person for non-Indigenous Australians ($579 compared with $857) (Table 3.15.1).

Pharmaceutical Benefits Scheme: Nationally in 2013–14, expenditure by the Department of Health through the PBS was $195 per person for Indigenous Australians, less than for non-Indigenous Australians ($374). Drugs supplied under Section 100 arrangements (which allows for PBS medicines to be provided to remote area Aboriginal and Torres Strait Islander primary health-care services) accounted for $48 per person of the total PBS expenditure for Indigenous Australians (Table 3.15.2).

Access to prescription medicines: In New South Wales in 2012–13, 20% of Indigenous Australians aged 15 and over in Non-remote areas reported they had a prescription that did not get filled in the previous 12 months. The most common reasons reported by Indigenous Australians for not having a prescription filled were: they decided they didn't need it (38%); the cost (25%); transport issues, lost the prescription, or other (18%); they were too busy (15%); and they didn't want to (14%).

Nationally, 19% of Indigenous Australians aged 15 and over in Non-remote areas reported they had a prescription that did not get filled in the previous 12 months. The most common reasons reported by Indigenous Australians for not having a prescription filled were: they decided they didn't need it (35%); the cost (34%); transport issues, lost the prescription, or other (19%); they didn't want to (14%); and they were too busy (11%) (Table 3.15.5, Figure 3.15.2).

Trend over time: Nationally, between 2010–11 and 2014–15, Australian Government expenditure on mainstream PBS and the Repatriation Schedule of Pharmaceutical Benefits (RPBS) for Indigenous Australians rose by 11.7%, from $106 to $119 per person. For non-Indigenous Australians, expenditure fell by 10.8% from $362 to $323 per person. Note that state and territory governments do not provide funds for the PBS or RPBS (Table 3.15.4, Figure 3.15.3).

Figure 3.15.3: Australian Government expenditure on mainstream PBS and RPBS per person, by Indigenous status, 2010–11 to 2014–15

3.16 Access to after-hours primary health care

Why it is important

This measure reports on access to after-hours primary health care. ‘After hours’ refers to services provided on Sundays, before 8 am and/or after 12 pm on a Saturday, or at any time other than 8 am to 6 pm on weekdays. An important component of comprehensive primary health-care services is the capacity for patients to access services after hours. In the absence of after-hours primary health care, patients with more urgent needs might delay seeking care (AHMAC 2017).

Key findings

**After-hours GP:** In New South Wales in 2012–13, 9% of all Indigenous Australians living in Non-remote areas reported seeing a doctor outside normal business hours in the previous 12 months.

Nationally, 9% of Indigenous Australians living in Non-remote areas reported seeing a doctor outside normal business hours in the previous 12 months (Table 3.16.1, Figure 3.16.1).

**Medicare:** In New South Wales in 2015–16, the rate for MBS services claimed by Indigenous Australians for after-hours care items was 383 per 1,000. The age-standardised rate for Indigenous Australians was 0.8 times the rate for non-Indigenous Australians (383 compared with 467 per 1,000).

Nationally, the rate for MBS services claimed by Indigenous Australians for after-hours care items was 400 per 1,000. The age-standardised rate for Indigenous Australians was 0.8 times the rate for non-Indigenous Australians (390 compared with 474 per 1,000) (Table 3.16.3, Figure 3.16.2).

**Emergency department presentations overall:** In New South Wales between 2014–15 and 2015–16, 59% of emergency department presentations for Indigenous patients occurred after hours, similar to the proportion for non-Indigenous patients (56%).

Nationally, 59% of emergency department presentations for Indigenous patients occurred after hours, similar to the proportion for non-Indigenous patients (56%) (Table 3.16.10, Figure 3.16.3).

**Emergency department presentations (semi-urgent or non-urgent):** In New South Wales between 2014–15 and 2015–16, 60% of emergency department presentations for Indigenous patients that occurred after hours were classified as semi-urgent or non-urgent (triage categories 4 and 5). This was higher than the proportion for non-Indigenous patients (54%).

Nationally, 55% of emergency department presentations for Indigenous patients that occurred after hours were classified as semi-urgent or non-urgent (triage categories 4 and 5). This was slightly higher than the proportion for non-Indigenous patients (50%) (Table 3.16.11).

Figure 3.16.2: Age-standardised rate of MBS services claims for after-hours care, by Indigenous status, New South Wales and Australia, 2015–16

Figure 3.16.3: Proportion of emergency department presentations that were after hours, by Indigenous status, New South Wales and Australia, 2014–15 to 2015–16

3.17 Regular GP or health service

Why it is important

This measure reports on people who have a regular GP or health service. Having a usual primary health-care provider is associated with good communication between the patient and provider, greater levels of trust and satisfaction with providers (Mainous et al. 2001; Schers et al. 2005) and better health outcomes for patients (Starfield 1998; Starfield & Shi 2004). Those with a usual primary care provider are more likely to receive care based on guidelines, preventive care and better coordination of care with other providers to meet patient need (Atlas et al. 2009; Forrest & Starfield 1996). Other benefits of having a continuous doctor–patient relationship include improved diagnoses, better medication management, avoidance of repeat tests or other interventions, and fewer hospitalisations, particularly for people with complex health-care needs (Hollander et al. 2009).

Key findings

**Overall:** In New South Wales in 2012–13, 85% of Indigenous Australians of all ages reported they had a usual place to go for health problems and advice.

Nationally, 86% of Indigenous Australians reported they had a usual place to go for health problems and advice (Table 3.17.1).

**Regular health care:** In New South Wales in 2012–13, Indigenous Australians who had a problem with their health reported that they usually went to a doctor or GP (63%), followed by Aboriginal Medical Services (17%) and hospitals (3%).

Nationally, 54% of Indigenous Australians who had a problem with their health reported that they usually went to a doctor or GP, 17% went to an Aboriginal Medical Services, 10% went to community clinics and 5% went to hospitals (Table 3.17.1, Figure 3.17.1).

**Health care available in local area:** In New South Wales in 2012–13, 93% of Indigenous Australians reported that a doctor or GP was locally available, 81% had a hospital available, and 50% had an Aboriginal Medical Services available.

Nationally, 83% of Indigenous Australians reported that a doctor or GP who was locally available, 71% had a hospital available, 48% had an Aboriginal Medical Services available, and 42% had a community clinic available (Table 3.17.1, Figure 3.17.2).

**Preferred health care:** In New South Wales in 2012–13, 61% of Indigenous Australians reported that they preferred to go to a doctor or GP for health problems or advice, followed by an Aboriginal Medical Services (32%), and hospital (4%).

Nationally, 53% of Indigenous Australians reported that they preferred to go to a doctor or GP for health problems or advice, followed by an Aboriginal Medical Services (26%), and hospital (10%) (Table 3.17.1, Figure 3.17.3).
3.18 Care planning for chronic diseases

Why it is important

This measure reports on care planning for the management of chronic disease. Chronic diseases are major causes of illness, disability and death among Indigenous Australians. An estimated 70% of the health gap between Indigenous and non-Indigenous Australians is attributed to chronic diseases (AIHW 2016b). Effective management of chronic diseases can delay the progression of disease, reduce the need for high-cost interventions, improve quality of life and increase life expectancy. Good quality care for people with chronic diseases generally involves multiple health-care providers across multiple settings. As a result, care plans are one way the client and primary health-care provider can ensure appropriate care is arranged and coordinated. GPs are encouraged to develop care plans through several items under the Medicare Benefits Schedule, including a GP Management Plan (GPMP) and a Team Care Arrangement (TCA) (AHMAC 2017).

Key findings

**GP Management Plan:** In New South Wales and the Australian Capital Territory combined, in May 2015, 52% of Indigenous clients of Indigenous primary health-care services with type 2 diabetes claimed a GPMP in the previous 2 years. Nationally, 51% of Indigenous clients of Indigenous primary health-care services with type 2 diabetes claimed a GPMP in the previous 2 years (Table 3.18.1, Figure 3.18.1).

**Team Care Arrangement:** In New South Wales and the Australian Capital Territory combined, in May 2015, 50% of Indigenous clients of Indigenous primary health-care services with type 2 diabetes claimed a TCA in the previous 2 years. Nationally, 48% of Indigenous clients of Indigenous primary health-care services with type 2 diabetes claimed a TCA in the previous 2 years (Table 3.18.1, Figure 3.18.1).

**Trend over time (GPMP):** In New South Wales and the Australian Capital Territory combined, the proportion of Indigenous clients of Indigenous primary health-care services with type 2 diabetes who claimed a GPMP rose from 46% in December 2012 to 52% in May 2015. Nationally, the proportion of Indigenous clients of Indigenous primary health-care services with type 2 diabetes who claimed a GPMP rose from 41% in December 2012 to 51% in May 2015 (Table 3.18.1, Figure 3.18.2).

**Trend over time (TCAs):** In New South Wales and the Australian Capital Territory combined, the proportion of Indigenous clients of Indigenous primary health-care services with type 2 diabetes who had a TCA rose from 44% in December 2012 to 50% in May 2015. Nationally, the proportion of Indigenous clients of Indigenous primary health-care services with type 2 diabetes who had a TCA rose from 36% in December 2012 to 48% in May 2015 (Table 3.18.1, Figure 3.18.3).
Figure 3.18.1: Proportion of Indigenous regular Indigenous primary health-care services clients with type 2 diabetes who had a GPMP or TCA in the previous 2 years, New South Wales and the Australian Capital Territory combined and Australia, May 2015

Figure 3.18.3: Proportion of Indigenous regular Indigenous primary health-care services clients with type 2 diabetes who had a TCA in the previous 2 years, New South Wales and the Australian Capital Territory combined and Australia, December 2012 to May 2015

3.19 Accreditation

Why it is important

This measure reports on the proportion of accredited public hospitals and accredited general medical practices. Accreditation is a process (usually voluntary) through which a recognised external body assesses the extent to which a health-care organisation meets applicable quality standards. Quality standards typically consider issues such as: governance of the organisation, management of safety issues such as infection control, handling of care processes such as discharge planning, general management issues such as human resource management, quality of the physical infrastructure, and issues such as handling of patient complaints (AHMAC 2017). Public and private hospitals are accredited against the National Safety and Quality Health Service Standards. Accreditation in general practice involves assessment against standards set by the Royal Australian College of General Practitioners. There are 2 registered general practice accreditation providers: Australian General Practice Accreditation Limited (AGPAL) and General Practice Accreditation Plus (GPA+) (AHMAC 2017).

Key findings

**Hospitals:** In New South Wales in 2014–2015, of the 85,666 hospitalisations in public hospitals for Indigenous Australians, 99.4% occurred in the 221 accredited hospitals. For non-Indigenous Australians, of the 1.7 million hospitalisations, 98.7% occurred in accredited hospitals (tables 3.19.1, 3.19.7, Figure 3.19.1).

Nationally, of the 400,068 hospitalisations in public hospitals for Indigenous Australians, 92% occurred in the 647 accredited hospitals. For non-Indigenous Australians, of the 5.5 million hospitalisations, 93% occurred in accredited hospitals (tables 3.19.3, 3.19.7, Figure 3.19.1).

**General practices (overall):** In New South Wales in 2014–15, 1,964 general practices were registered for accreditation through AGPAL or GPA+. Of these, 93% had been accredited (Table 3.19.5 NSW, Figure 3.19.2).

Nationally, 5,879 general practices were registered for accreditation through AGPAL or GPA+. Of these, 92% had been accredited (Table 3.19.5, Figure 3.19.2).

**General practices (Primary Health Network):** In New South Wales in 2014–15, the proportion of general practices registered within a Primary Health Network (PHN) with GPA+ or AGPAL that were fully accredited ranged from 88% (190 practices) in South Western Sydney to 99% (76 practices) in Murrumbidgee (Table 3.19.8).

**General practices (proportion of the population that is Indigenous within a PHN):** In New South Wales in 2014–15, the proportion of practices that were accredited varied from 89% for practices in PHNs where Indigenous Australians made up 3%–4% of the population, to 98% in PHNs where 10% or more of the population was Indigenous (Table 3.19.5 NSW, Figure 3.19.3).

Nationally, the proportion of practices that were accredited ranged from 92% for practices in PHNs where Indigenous Australians made up less than 2% of the population, to 95% in PHNs where 10% or more of the population was Indigenous (Table 3.19.5, Figure 3.19.3).
Figure 3.19.1: Hospitalisation in accredited public hospitals, by Indigenous status, New South Wales and Australia, 2014–15

Figure 3.19.2: Proportion of general practices registered for accreditation through AGPAL or GPA+ that had been accredited, New South Wales and Australia, 2014–2015

Figure 3.19.3: Proportion of general practices registered for accreditation through AGPAL or GPA+ that had been accredited, by percentage of the population that was Indigenous, New South Wales and Australia, 2014–2015

3.20 Aboriginal and Torres Strait Islander peoples training for health-related disciplines

Why it is important

This measure reports on the proportion of Indigenous Australians in tertiary education for health-related disciplines. Indigenous Australians are significantly under-represented in the health workforce. Improving and supporting the participation of Indigenous Australians in tertiary education for health-related disciplines is vital to increasing Indigenous Australians participation in the health workforce (AHMAC 2017).

Key findings

Tertiary education enrolment: In New South Wales in 2015, there were 681 Indigenous students enrolled in undergraduate domestic health-related courses, a rate of 46 per 10,000 Indigenous Australians aged 15 and over. This was 1.2 times the rate for non-Indigenous Australians (39 per 10,000).

Nationally, 2,001 Indigenous students enrolled in undergraduate domestic health-related courses, a rate of 42 per 10,000 Indigenous Australians aged 15 and over. This was 0.8 times the rate for non-Indigenous Australians (55 per 10,000) (Table 3.20.27, Figure 3.20.1).

Tertiary education completion: In New South Wales in 2015, 110 Indigenous students completed their undergraduate domestic health-related courses, a rate of 7.4 per 10,000 Indigenous Australians aged 15 and over. This was 0.9 times the rate for non-Indigenous Australians (8.4 per 10,000).

Nationally, 270 Indigenous students completed their undergraduate domestic health-related courses, a rate of 5.6 per 10,000 Indigenous Australians aged 15 and over. This was 0.5 times the rate for non-Indigenous Australians (10.5 per 10,000) (Table 3.20.27, Figure 3.20.2).

Vocational education and training enrolment: In New South Wales in 2015, 950 vocational education and training (VET) students aged 15 and over enrolled in health-related courses were Indigenous. This represents 8.3% of total VET students aged 15 and over enrolled in health-related courses.

Nationally, 3,021 VET students aged 15 and over enrolled in health-related courses were Indigenous. This represents 4.7% of total VET students enrolled in health-related courses (Table 3.20.12, Figure 3.20.3).

Vocational education and training completion: In New South Wales in 2015, 262 VET students aged 15 and over who completed health-related courses were Indigenous, representing 6% of total completions.

Nationally, 799 VET students aged 15 and over who completed health-related courses were Indigenous, representing 3.8% of total completions (Table 3.20.36).

Aboriginal and Torres Strait Islander Health Performance Framework 2017: New South Wales  155
3.21 Expenditure on Aboriginal and Torres Strait Islander health compared to need

Why it is important

This measure reports on health-related expenditure. A basic principle of equity is that health expenditure should reflect the relative needs for health services (Braveman & Gruskin 2003; Whitehead 1992). Health expenditure for population groups with higher levels of need should be proportionately higher. A broad assessment of how well this principle is implemented is provided by comparing differentials in health status with differences in per capita health expenditure (AHMAC 2017).

Key findings

**Overall:** In New South Wales in 2013–14, the state government health expenditure per person for Indigenous Australians was $3,515, 1.5 times the health expenditure per person for non-Indigenous Australians ($2,374).

Nationally, the average state or territory government health spending per person for Indigenous Australians was $4,890, twice the health expenditure per person for non-Indigenous Australians ($2,425) (Table 3.21.3, Figure 3.21.1).

**Public hospital services:** In New South Wales in 2013–14, health spending per person on public hospital services was 1.6 times as high for Indigenous Australians as for non-Indigenous Australians ($2,991 compared with $1,909).

Nationally, health expenditure per person on public hospital services was 2.1 times as high for Indigenous Australians as for non-Indigenous Australians ($3,959 compared with $1,868) (Table 3.21.3, Figure 3.21.2).

**Community health services:** In New South Wales in 2013–14, health expenditure per person on community health services was $253 for Indigenous and non-Indigenous Australians.

Nationally, health expenditure per person on community health services for Indigenous Australians was 1.3 times the rate for non-Indigenous Australians ($372 compared with $284) (Table 3.21.3).

**Patient transport services:** In New South Wales in 2013–14, health expenditure per person on patient transport services for Indigenous Australians was 1.6 times the rate for non-Indigenous Australians ($174 compared with $108).

Nationally, health expenditure per person on patient transport services was 2.2 times as high for Indigenous Australians as for non-Indigenous Australians ($255 compared with $115) (Table 3.21.3).

**Public health services:** Public health services are provided or funded by governments, and are aimed at protecting and promoting health, and preventing illness or injury in the whole population or specific population subgroups.

In New South Wales in 2013–14, health expenditure per person on public health services for Indigenous Australians was 0.9 times the rate for non-Indigenous Australians ($60 compared with $68).

Nationally, health expenditure per person on public health services for Indigenous Australians was 1.7 times as the rate for non-Indigenous Australians ($121 compared with $71) (Table 3.21.3, Figure 3.21.3).

Figure 3.21.3: Public health services expenditure per person, by Indigenous status, New South Wales and Australia, 2013–14

3.22 Recruitment and retention of staff

Why it is important

This measure reports on the recruitment and retention of qualified clinical and management staff to provide effective health care. The capacity to recruit and retain appropriate staff is critical to the appropriateness, continuity and sustainability of health services including Aboriginal and Torres Strait Islander primary health-care services. Staff recruitment and retention is particularly important in regional, rural and remote areas because 65% of Indigenous Australians live outside the major cities (AHMAC 2017). Aboriginal Community Controlled Health Organisations (ACCHO) are non-government organisations operated by local Aboriginal and Torres Strait Islander communities to deliver health care to communities that control them (NACCHO 2015). There are more ACCHOs than any other type of health service organisations in all remoteness areas, making them an ideal indicator for the scope of health-care services for Indigenous Australians (AIHW 2016e).

Key findings

Medical practitioners: In New South Wales in 2015, there were 30,578 registered medical practitioners (which includes general practitioners, specialists, hospital non-specialists, specialists in training, and non-clinicians). Of these, 92% were employed in medicine. Nationally in 2015, there were 97,466 registered medical practitioners. Of these, 90% were employed in medicine (Table 3.22.1, Figure 3.22.1).

Nurses and midwives: In New South Wales in 2015, there were 99,505 nurses and midwives. Of these, 94% were employed in nursing or midwifery. Nationally in 2015, there were 360,008 nurses or midwives. Of these, 93% were employed in nursing or midwifery (Table 3.22.10, Figure 3.22.1).

GPs employed in Indigenous specific health services (ISHP): In New South Wales and the Australian Capital Territory combined, between June 2014 and May 2015, there were 1.2 full-time equivalent (FTE) GPs per 1,000 clients in the ACCHOs. For other ISHPs, there were 0.3 FTE GPs per 1,000 clients. Nationally, there were 1.3 FTE GPs per 1,000 clients in the ACCHOs. For other ISHPs, there were 0.8 FTE GPs per 1,000 clients (AIHW 2016e, Figure 3.22.2).

Vacant full-time medical positions in ISHPs: In New South Wales and the Australian Capital Territory combined, between June 2014 and May 2015, there were 0.3 vacant FTE positions per 1,000 clients in the ACCHOs. For other ISHPs, there were 0.4 vacant FTE positions per 1,000 clients. Nationally, between June 2014 and May 2015, there were 0.6 vacant FTE positions (including visiting staff) per 1,000 clients in the ACCHOs. For other ISHPs, there were 0.9 vacant FTE positions per 1,000 clients (AIHW 2016e; Figure 3.22.3).

Glossary

**Aboriginal or Torres Strait Islander:** A person of Aboriginal and/or Torres Strait Islander descent who identifies as an Aboriginal and/or Torres Strait Islander. See also **Indigenous**.

**additional diagnosis:** A condition or complaint that either coexists with the principal diagnosis or arises during an episode of admitted patient care. An additional diagnosis is reported if the condition affects patient management. Compare with **principal diagnosis**.

**age-specific rate:** An estimate of the proportion of people experiencing a particular event in a specified age group relative to the total number of people who are at risk of that event in that age group. See also **crude rate**.

**age-standardised rates:** Rates adjusted for age to take into account differences in age structures when comparing different populations or across time.

**associated cause(s) of death:** All causes listed on the death certificate, other than the underlying cause of death. They include the immediate cause, any intervening causes, and conditions that contributed to the death, but were not related to the disease or condition causing the death. See also **cause of death**.

**cause of death:** All diseases, morbid conditions, or injuries that either resulted in or contributed to death, and the circumstances of the accident or violence that produced the injuries, as entered on the medical certificate of cause of death. Causes of death are commonly reported using the underlying cause of death. See also **associated cause(s) of death**.

**crude rate:** An estimate of the proportion of a population that experiences an outcome during a specified period. It is calculated by dividing the number of people with the outcome in a specified period by the number of people in the population during that period.

**determinant:** A factor that can increase the chances of ill health (risk factor) or good health (protective factor) in a population or individual. By convention, services or other programs that aim to improve health are usually not included.

**dialysis:** A process used to treat kidney failure. A machine is connected to the patient’s bloodstream to filter the blood externally to the body, removing water, excess substances and waste from the blood, as well as regulating the levels of circulating chemicals. In doing this, the machine takes on the role normally played by the kidneys.

**external cause:** The term used in disease classification to refer to an event or circumstance in a person’s external environment that is regarded as a cause of injury or poisoning.

**gap:** In this report, the gap refers to the rate difference.

**hospitalisation (or separation):** An episode of admitted patient care, which can be a total hospital stay (from admission to discharge, transfer, or death), or a portion of a hospital stay beginning or ending in a change of type of care (for example, from acute care to rehabilitation).

**household:** A group of 2 or more related or unrelated people who usually live in the same dwelling, and who make common provision for food or other essentials for living, or an individual living in a dwelling who makes provision for his or her own food and other essentials for living, without combining with any other person.

**incidence:** The number of new cases (of an illness or event) occurring during a given period. Compare with **prevalence**.
**Indigenous:** A person of Aboriginal and/or Torres Strait Islander descent who identifies as an Aboriginal and/or Torres Strait Islander. See also *Aboriginal or Torres Strait Islander*.

**non-Indigenous:** People who have indicated they are not of Aboriginal or Torres Strait Islander descent. Compare with *other Australians*.

**other Australians:** Includes people who do not identify as being of Aboriginal or Torres Strait Islander origin, and people for whom information on their Indigenous status was not available. Compare with *non-Indigenous*.

**prevalence:** The number or proportion (of cases, instances, and so on) in a population at a given time. Compare with *incidence*.

**principal diagnosis:** The diagnosis established after study to be chiefly responsible for occasioning a patient’s episode of admitted patient care. Compare with *additional diagnosis*.

**remoteness areas:** A classification of the remoteness of a location using the Australian Statistical Geography Standard Remoteness Structure, based on the Accessibility/Remoteness Index of Australia, which measures the remoteness of a point based on the physical road distance to the nearest urban centre (ABS 2013b).

**statistical significance:** An indication from a statistical test that an observed difference or association may be significant or ‘real’, because it is unlikely to be due just to chance. In this report, references to ‘significant’ or ‘statistically significant’ differences refer to differences at the p < 0.05 level—that is, there is less than a 1 in 20 chance that the result occurred by chance. The words ‘significant’ and ‘significantly’ are not used in this report other than in their statistical context.

**underlying cause of death:** The disease or injury that initiated the sequence of events leading directly to death, or the circumstances of the accident or violence that produced the fatal injury. See also *cause of death* and *associated cause(s) of death*.

Aboriginal and Torres Strait Islander Health Performance Framework 2017: New South Wales  179
Figure 2.16.2: Age-standardised rate of adults (aged 18 and over) who reporting engaging in short-term/single occasion alcohol risk, by remoteness area and Indigenous status, New South Wales and Australia, 2012–13 .......................... 101

Figure 2.16.3: Age-standardised hospitalisation rate related to alcohol use, by Indigenous status, New South Wales and NSW, Vic, Qld, WA, SA and NT combined), 2004–05 to 2014–15 .................................................................................................. 101

Figure 2.17.1: Proportion of Indigenous Australians (aged 15 and over) who reported using illicit drugs or other substances in the previous 12 months, by sex, New South Wales and Australia, 2014–15 .................................................................................. 103

Figure 2.17.2: Proportion of Indigenous children (aged 0–3) whose mothers used illicit drugs or substances during pregnancy, New South Wales and Australia, 2014–15 ........................................................................................................... 103

Figure 2.17.3: Proportion of detainees who provided urine during selected state collections who tested positive to a drug, by Indigenous status, New South Wales, 2004–2015 .................................................................................................................. 103

Figure 2.18.1: Age-standardised rate of Australians (aged 18 and over) with sufficient physical activity, by Indigenous status, New South Wales and Australia (Non-remote areas), 2012–13 ........................................................................................................ 105

Figure 2.18.2: Proportion of Indigenous children (aged 4–14) who were physically active every day for at least 60 minutes, New South Wales and Australia, 2008 and 2014–15 .................................................................................................................... 105

Figure 2.18.3: Proportion of Indigenous children (aged 4–14) who were physically active for at least 60 minutes in the previous week, by number of days, New South Wales and Australia, 2014–15 ......................................................................................... 105

Figure 2.19.1: Proportion of Indigenous Australians (aged 12 and over) reported to eat less than 1 serve of fruit per day, by remoteness area, New South Wales and Australia, 2014–15 ........................................................................................................ 107

Figure 2.19.2: Proportion of Indigenous Australians (aged 12 and over) reported to eat less than 1 serve of vegetables per day, by remoteness area, New South Wales and Australia, 2014–15 ......................................................................................... 107

Figure 2.19.3: Proportion of Indigenous children (aged 2–14), by number of serves of fruit and vegetables consumed daily, New South Wales and Australia, 2014–15 ........................................................................................................ 107

Figure 2.20.1: Breastfeeding status of Indigenous children (aged 0–3 years), New South Wales and Australia, 2014–2015 .......................................................................................................................... 109

Figure 2.20.2: Time infants (aged 0–2 years) were breastfed, by Indigenous status, New South Wales and Australia, 2014–15 .......................................................................................................................... 109

Figure 2.20.3: Breastfeeding status of Indigenous infants (aged 0–3), by remoteness area, Australia, 2004–05, 2008, 2012–13, and 2014–15 ......................................................................................................................... 109

Figure 2.21.1: Age-standardised rate of mothers who smoked during pregnancy, by Indigenous status, New South Wales and Australia, 2014 ........................................................................................................... 111

Figure 2.21.2: Alcohol consumption by of mothers of Indigenous children (aged 0–3) during pregnancy, New South Wales and Australia, 2014–15 ........................................................................................................... 111

Figure 2.21.3: Illicit drug or substance use by mothers of Indigenous children (aged 0–3) during pregnancy, New South Wales and Australia, 2014–15 ........................................................................................................... 111
Figure 2.22.1: Proportion of Indigenous Australians (aged 15 and over) who were overweight or obese (measured data), New South Wales and Australia, 2012–13 .............................................................. 113

Figure 2.22.2: Age-standardised rate (number per 100 population) of overweight or obese people aged 18 and over, by remoteness area and Indigenous status, New South Wales and Australia, 2012–13 ......................................................... 113

Figure 2.22.3: Proportion of Indigenous Australians (aged 15 and over) who reported they were obese, by selected socioeconomic characteristics, Australia, 2012–13 ........................................................................................................... 113

Figure 3.01.1: Age-standardised rate of mothers attending at least 1 antenatal visit, by Indigenous status, New South Wales and Australia, 2014 ................................................................. 117

Figure 3.01.2: Age-standardised rate of mothers attending their first antenatal session, by duration of pregnancy and Indigenous status, New South Wales and Australia, 2014 ................................................................................................. 117

Figure 3.01.3: Proportion of mothers of Indigenous children (aged 0–3) who had regular pregnancy check-ups, and sought advice or information about pregnancy or childbirth, New South Wales and Australia, 2014–15 ................................................................. 117

Figure 3.02.1: Vaccination coverage for children at age 1, by selected diseases and Indigenous status, New South Wales and Australia, 31 December 2015 ..... 119

Figure 3.02.2: Vaccination coverage for children vaccinated at age 2, by selected diseases and Indigenous status, New South Wales and Australia, 31 December 2015 ................................................................. 119

Figure 3.02.3: Vaccination coverage for children vaccinated at age 5, by selected diseases and Indigenous status, New South Wales and Australia, 31 December 2015 .......................................................................................... 119

Figure 3.03.1: Proportion of Indigenous Australians (aged 15 and over) who discussed lifestyle with a GP or health professional, New South Wales and Australia, 2012–13 ........................................................................................................... 121

Figure 3.03.2: Issues (multiple responses allowed) Indigenous Australians (aged 15 and over), discussed with a GP or health professional in the previous 12 months, by lifestyle issue, New South Wales and Australia, 2012–13..... 121

Figure 3.03.3: Proportion of Aboriginal and Torres Strait Islander primary health-care organisations providing health promotion, by type of program or activity (multiple responses allowed), New South Wales and Australia, June 2014 to May 2015 ................................................................. 121

Figure 3.04.1: Rate of Indigenous-specific health checks claimed (MBS item 715), Indigenous Australians, by age group (years), New South Wales and Australia, 2015–16 ........................................................................................................... 123

Figure 3.04.2: Age-standardised participation rates in BreastScreen Australia programs for women aged 50–69, by Indigenous status, New South Wales and Australia, 2013–2014 ........................................................................................................... 123

Figure 3.04.3: Rate of Indigenous-specific health checks claimed (MBS item 715), Indigenous Australians, by age group (years), New South Wales and Australia, 2006–07 to 2015–16 ........................................................................................................... 123

Figure 3.05.1: Proportion with diagnosed, current, and long-term diabetes or high sugar levels who had an HbA1C test in the previous 12 months, by Indigenous status, New South Wales and Australia, 2012–13 ................................................................. 125
Figure 3.05.2: Actions taken to manage diabetes or high sugar levels, Indigenous Australians, New South Wales and Australia, 2012–13 ......................................................... 125

Figure 3.05.3: Proportion of Indigenous regular clients with type 2 diabetes who had a GPMP or TCA in the last 2 years, Indigenous primary health care services, NSW and ACT combined and Australia, December 2012 to May 2015............... 125

Figure 3.06.1: Age-standardised proportion of hospitalisations with a procedure recorded, by Indigenous status, New South Wales and Australia, July 2013 to June 2015................................................................. 127

Figure 3.06.2: Age-standardised rate of hospitalisations with a procedure recorded, by diagnosis and Indigenous status, New South Wales and Australia, July 2013 to June 2015................................................................. 127

Figure 3.07.1: Age-standardised hospitalisation rate for potentially preventable hospitalisations, by sex and Indigenous status, New South Wales and Australia, July 2013 to June 2015................................................................. 129

Figure 3.07.2: Age-standardised hospitalisation rate for potentially preventable hospitalisations, by condition and Indigenous status, New South Wales and Australia, July 2013 to June 2015................................................................. 129

Figure 3.07.3: Hospitalisation rate for potentially preventable hospitalisations, by age group (years) and Indigenous status, New South Wales and Australia, July 2013 to June 2015................................................................. 129

Figure 3.08.1: Proportion of Indigenous Australians who didn’t access a health provider when needed, by health provider type, New South Wales and Australia, 2012–13.................................................................................................................. 131

Figure 3.08.2: Proportion of Indigenous Australians who didn’t access a health provider when needed who reported this was due to logistical reasons or cultural appropriateness of service, by health provider type, New South Wales and Australia, 2012–13.................................................................................................................. 131

Figure 3.08.3: Patient experience, Indigenous Australians (aged 15 and over), by type of doctor behaviour, New South Wales and Australia (Non-remote areas), 2012–13.................................................................................................................. 131

Figure 3.09.1: Age-standardised rate of hospitalisation where the patient left against medical advice/discharged at own risk, by Indigenous status, New South Wales and Australia, 2013–14 to 2014–15......................................................... 133

Figure 3.09.2: Proportion of hospitalisations where the patient left against medical advice/discharged at own risk, by age group (years) and Indigenous status, New South Wales and Australia, July 2013 to June 2015......................................................... 133

Figure 3.09.3: Age-standardised rate of hospitalisations where Indigenous patients left against medical advice/were discharged at own risk, by diagnosis, New South Wales and Australia, July 2013 to June 2015......................................................... 133

Figure 3.10.1: Age-standardised rate of community mental health service contacts, by Indigenous status, New South Wales and Australia, 2014–15................................. 135

Figure 3.10.2: Age-standardised rate of residential mental health-care episodes, by Indigenous status, New South Wales and Australia, 2014–15................................. 135

Figure 3.10.3: Age-standardised hospitalisation rate for mental health related-conditions, by Indigenous status, New South Wales and NSW, Vic, Qld, WA, SA and NT combined, 2004–05 to 2014–15 .......................................................... 135
Figure 3.11.1: Proportion of Indigenous Australians (aged 15 and over) reporting substance use in previous 12 months, by sex, New South Wales and Australia, 2014–15

Figure 3.11.2: Proportion of Aboriginal and Torres Strait Islander primary health-care organisations providing health promotion, by type of activity, New South Wales and the Australian Capital Territory combined and Australia, 1 June 2014 to 31 May 2015

Figure 3.11.3: Age-standardised hospitalisations related to alcohol use, by sex and Indigenous status, New South Wales and Australia, July 2013 to June 2015

Figure 3.12.1: Rate of employed health professionals, by Indigenous status, New South Wales and Australia, 2014 and 2015

Figure 3.12.2: Rate of employed medical practitioners, by Indigenous status, New South Wales and Australia, 2015

Figure 3.12.3: Rate of employed nurses and midwives, by Indigenous status, New South Wales and Australia, 2015

Figure 3.13.1: Governing committee or board information, Aboriginal and Torres Strait Islander primary health-care services, New South Wales and Australia, 1 June 2014 to 31 May 2015

Figure 3.13.2: Aboriginal and Torres Strait Islander substance-use services, governing committee or board information, New South Wales and Australia, 1 June 2014 to 31 May 2015

Figure 3.13.3: Proportion of Aboriginal and Torres Strait Islander primary health-care services participating in mainstream processes, New South Wales and Australia, 1 June 2014 to 31 May 2015

Figure 3.14.1: Self-reported rate of Indigenous Australians accessing health-care services, by type of service, New South Wales and Australia, 2012–13

Figure 3.14.2: Age-standardised rate of total MBS services claimed, by Indigenous status, New South Wales and Australia, 2015–16

Figure 3.14.3: Age-standardised rate of hospitalisation for palliative care, by sex and Indigenous status, New South Wales and Australia, July 2013 to June 2015

Figure 3.15.1: Proportion of Indigenous Australians (aged 15 and over) who had a prescription that was not filled in the previous 12 months, New South Wales and Australia (Non-remote areas), 2012–13

Figure 3.15.2: Reasons for not filling prescriptions, Indigenous Australians (aged 15 and over), New South Wales and Australia (Non-remote areas), 2012–13

Figure 3.15.3: Australian Government expenditure on mainstream PBS and RPBS per person, by Indigenous status, 2010–11 to 2014–15

Figure 3.16.1: Proportion of Indigenous Australians reporting they had seen a doctor or GP after hours, New South Wales and Australia (Non-remote areas), 2012–13

Figure 3.16.2: Age-standardised rate of MBS services claims for after-hours care, by Indigenous status, New South Wales and Australia, 2015–16
Figure 3.16.3: Proportion of emergency department presentations that were after hours, by Indigenous status, New South Wales and Australia, 2014–15 to 2015–16 ........................................................................................................... 147

Figure 3.17.1: Types of regular health care used by Indigenous Australians, New South Wales and Australia, 2012–13 ...................................................... 149

Figure 3.17.2: Health services available in local area for Indigenous Australians, New South Wales and Australia, 2012–13 ...................................................... 149

Figure 3.17.3: Types of health care preferred by Indigenous Australians, New South Wales and Australia, 2012–13 ...................................................... 149

Figure 3.18.1: Proportion of Indigenous regular Indigenous primary health-care services clients with type 2 diabetes who had a GPMP or TCA in the previous 2 years, New South Wales and the Australian Capital Territory combined and Australia, May 2015 .................................................................................. 151

Figure 3.18.2: Proportion of Indigenous regular Indigenous primary health-care services clients with type 2 diabetes who had a GPMP in the previous 2 years, New South Wales and the Australian Capital Territory combined and Australia, December 2012 to May 2015 .......................................................... 151

Figure 3.18.3: Proportion of Indigenous regular Indigenous primary health-care services clients with type 2 diabetes who had a TCA in the previous 2 years, New South Wales and the Australian Capital Territory combined and Australia, December 2012 to May 2015 .......................................................... 151

Figure 3.19.1: Hospitalisation in accredited public hospitals, by Indigenous status, New South Wales and Australia, 2014–15 ...................................................... 153

Figure 3.19.2: Proportion of general practices registered for accreditation through AGPAL or GPA+ that had been accredited, New South Wales and Australia, 2014–2015 ....................................................................................................... 153

Figure 3.19.3: Proportion of general practices registered for accreditation through AGPAL or GPA+ that had been accredited, by percentage of the population that was Indigenous, New South Wales and Australia, 2014–2015 ....................... 153

Figure 3.20.1: Undergraduate domestic health-related courses enrolments, by Indigenous status, New South Wales and Australia, 2015 ................................................ 155

Figure 3.20.2: Undergraduate domestic health-related courses completions, by Indigenous status, New South Wales and Australia, 2015 ................................................ 155
